Let "ACD"

Multiplying a Sequence of Matrices

(This example is from Section 15.2 in CormenLRS' book.)

MULTIPLICATION OF n MATRICES Given as input a sequence of n matrices $(A_1 \times A_2 \times \cdots \times A_n)$. Minimize the number of operation in the computation $A_1 \times A_2 \times \cdots \times A_n$

Recall that Given matrices A_1, A_2 with $\dim(A_1) = p_0 \times p_1$ and $\dim(A_2) = p_1 \times p_2$, the basic algorithm to $A_1 \times A_2$ takes time at most $p_0 p_1 p_2$.

Example:

$$\begin{bmatrix} 2 & 3 \\ 3 & 4 \\ 4 & 5 \end{bmatrix} \times \begin{bmatrix} 2 & 3 & 4 \\ 3 & 4 & 5 \end{bmatrix} = \begin{bmatrix} 13 & 18 & 23 \\ 18 & 25 & 32 \\ 23 & 32 & 41 \end{bmatrix}$$

MULTIPLYING A SEQUENCE OF MATRICES

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for opt sol

Optimal solution

DP on trees

- Matrix multiplication is NOT **commutative**, so we can not permute the order of the matrices without changing the result.
- It is **associative**, so we can put parenthesis as we wish.
- **How to multiply** is equivalent to the problem of **how to parenthesize**.
- We want to find the way to put parenthesis so that the product requires the minimum total number of operations. And use it to compute the product.

Example Consider $A_1 \times A_2 \times A_3$, where $\dim(A_1) = 10 \times 100$, $\dim(A_2) = 100 \times 5$ and $\dim(A_3) = 5 \times 50$.

- $((A_1 A_2) A_3)$ takes $(10 \times 100 \times 5) + (10 \times 5 \times 50) =$
7500 operations,
- $(A_1 (A_2 A_3))$ takes $(100 \times 5 \times 50) + (10 \times 100 \times 50) =$
75000 operations.

The order in which we make the computation of products of two matrices makes a big difference in the total computation's time.

How to parenthesize $(A_1 \times \dots \times A_n)$?

- If $n = 1$ we do not need parenthesis.
- Otherwise, decide where to break the sequence $((A_1 \times \dots \times A_k)(A_{k+1} \times \dots \times A_n))$ for some k , $1 \leq k < n$.
- Then, combine any way to parenthesize $(A_1 \times \dots \times A_k)$ with any way to parenthesize $(A_{k+1} \times \dots \times A_n)$.

Using this structure, we can **count the number of ways** to parenthesize $(A_1 \times \dots \times A_n)$ as well as to **define a backtracking** algorithm that goes over all those ways to parenthesize and eventually to a **brute force recursive** algorithm to solve the problem of computing efficiently the product.

How many ways to parenthesize $(A_1 \times \cdots \times A_n)$?

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for opt sol

Optimal solution

DP on trees

Let $P(n)$ be the number of ways to parenthesize $(A_1 \times \cdots \times A_n)$. Then,

$$P(n) = \begin{cases} 1 & \text{if } n = 1 \\ \sum_{k=1}^{n-1} P(k)P(n-k) & \text{if } n \geq 2 \end{cases}$$

with solution $P(n) = \frac{1}{n+1} \binom{2n}{n} = \Omega(4^n / n^{3/2})$

The Catalan numbers.

Brute force will take too long!

Structure of an optimal solution

- We want to compute $(A_1 \times \cdots \times A_n)$ efficiently.
- In an optimal solution the last matrix product must correspond to a break at some position k ,
 $((A_1 \times \cdots \times A_k)(A_{k+1} \times \cdots \times A_n))$ Let
 $A_{i-j} = (A_i A_{i+1} \cdots A_j)$.
- The parenthesization of the subchains $(A_1 \times \cdots \times A_k)$ and $(A_{k+1} \times \cdots \times A_n)$ within the optimal parenthesization must be an optimal parenthesization of $(A_1 \times \cdots \times A_k)$, $(A_{k+1} \times \cdots \times A_n)$. So,

$$\begin{aligned} \text{cost}(A_1 \dots A_n) = & \text{cost}(A_1 \dots A_k) \\ & + \text{cost}(A_{k+1} \dots A_n) + p_0 p_k p_n. \end{aligned}$$

Structure of an optimal solution

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for opt sol

Optimal solution

DP on trees

- An optimal solution decomposes in optimal solutions of the same problem on subchains.
- Subproblems: compute the product $A_i \times A_{i+1} \times \cdots \times A_j$, for $1 \leq i \leq j \leq n$
- Let us call $B_i^j = A_i \times A_{i+1} \times \cdots \times A_j$.

Cost Recurrence

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for optimal sol

Optimal solution

DP on trees

- Let $m[i, j]$ be the minimum cost of computing $B_i^j = (A_i \times \dots \times A_j)$, for $1 \leq i \leq j \leq n$.
- $m[i, j]$ is defined by the value k , $i \leq k \leq j$ that minimizes

$$m[i, k] + m[k + 1, j] + \text{cost}(B_i^k, B_{k+1}^j).$$

- That is,

$$m[i, j] = \begin{cases} 0 & \text{if } i = j \\ \min_{i \leq k < j} \{m[i, k] + m[k + 1, j] + p_{i-1}p_kp_j\} & \text{otherwise} \end{cases}$$

Dynamic programming: Tabulating

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for optimal sol

Optimal solution

DP on trees

Assume that vector P holds the values (p_0, p_1, \dots, p_n) .

To compute the element $m[i, j]$ the base case is when $i = j$, we need to access $m[i, k]$ and $m[k + 1, j]$. We can achieve that by filling the (half) table by diagonals.

Dynamic programming: Tabulating

Recording more information about the optimal solution

We have been working with the recurrence

$$m[i, j] = \begin{cases} 0 & \text{if } i = j \\ \min_{i \leq k < j} \{m[i, k] + m[k + 1, j] + p_{i-1}p_kp_j\} & \text{otherwise} \end{cases}$$

To keep information about the optimal solution the algorithm keep additional information about the value of k that provides the optimal cost as

$$s[i, j] = \begin{cases} i & \text{if } i = j \\ \arg \min_{i \leq k < j} \{m[i, k] + m[k + 1, j] + p_{i-1}p_kp_j\} & \text{otherwise} \end{cases}$$

Computing optimally the product

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for optimal sol

Optimal solution

DP on trees

- $s[i, j]$ contains the value of k that decomposes optimally the product as product of two submatrices, i.e.,

$$A_i \times \cdots \times A_j = (A_i \times \cdots \times A_{s[i, j]})(A_{s[i, j]+1} \times \cdots \times A_j).$$

- Therefore,

$$A_1 \times \cdots \times A_n = (A_1 \times \cdots \times A_{s[1, n]})(A_{s[1, n]+1} \times \cdots \times A_n).$$

- We can design a recursive algorithm to perform the product in an optimal way.

The product algorithm

The input is the sequence of matrices $A = A_1, \dots, A_n$ and the table s computed before.

```
Product( $A, s, i, j$ )  
if  $i = j$  then  
    return ( $A_i$ )  
 $X = \mathbf{Product}(A, s, i, s[i, j])$   
 $Y = \mathbf{Product}(A, s, s[i, j] + 1, j)$   
return ( $X \times Y$ )
```

The total number operations required to compute the product is $m[1, n]$ and the cost of the complete algorithm is

$$T(n) = O(n^3 + m[1, n])$$

Multiplying

- In order to compute s , we only need the dimensions of the matrices.
- What if we use Strassen algorithm to compute a two matrices product instead of the naive algorithm?

Dynamic Programming in Trees

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for opt sol

Optimal solution

DP on trees

- Trees are nice graphs easily adapted to recursion.
- Once you root the tree each node can be seen as the root of a subtree .
- We can use Dynamic Programming to give polynomial solutions to "difficult" graph problems when the input is restricted to be a tree, or to have a tree-like structure (small treewidth).
- In this case instead of having a global table, each node in the tree keeps additional information about the associated subproblem.

The MAXIMUM WEIGHT INDEPENDENT SET (MWIS)

Given as input $G = (V, E)$, together with a weight $w : V \rightarrow \mathbb{R}$. Find the heaviest $S \subseteq V$ such that no two vertices in S are connected in G .

For general graphs, the problem is hard, even for the case in which all vertex have weight 1, i.e. MAXIMUM INDEPENDENT SET is NP-complete.

MAXIMUM WEIGHT INDEPENDENT SET on Trees

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for opt sol

Optimal solution

DP on trees

Given a tree $T = (V, E)$ choose a $r \in V$ and root it from r

i.e. Given a rooted tree

$T = (V, E, r)$ and weights

$w : V \rightarrow \mathbb{R}$, find the independent set with maximum weight.

Notation:

- For $v \in V$, let T_v be the subtree rooted at v . $T = T_r$.
- Given $v \in V$ let $C(v)$ be the set of children of v , and $G(v)$ be the set of grandchildren of v .

Characterization of the optimal solution

Multiplying matrices

The problem

Optimal substructure

Cost of an optimal sol

Adding info for opt sol

Optimal solution

DP on trees

Key observation: An IS can't contain vertices which are father-son.

Let S be an optimal solution.

- If $r \in S$: then $C(r) \not\subseteq S_r$. So $S - \{r\}$ contains an optimum solution for each T_v , with $v \in G(r)$.
- If $r \notin S$: S contains an optimum solution for each T_u , with $u \in C(r)$.

Recursive definition of the optimal solution

- To implement DP, for every node v , we add one value, $v.M$: the value of the optimal solution for T_v . Following the recursive structure of the solution we have the following recurrence

$$v.M = \begin{cases} w(v) & v \text{ a leaf,} \\ \max\{\sum_{u \in C(v)} u.M, w(v) + \sum_{u \in G(v)} u.M\} & \text{otherwise.} \end{cases}$$

- Notice that for any $v \in T$: we have to compute $\sum_{u \in C(v)} u.M$ and for this we must access to the children of its children
- To avoid this we add another value to the node $v.M'$: the sum of the values of the optimal solutions of their children, i.e., $\sum_{u \in C(v)} u.M$.

Post-order traversal of a rooted tree

To perform the computation, we can follow a DFS, post-order, traversal of the nodes in the tree, computing the additional values at each node.
