Interacting with computers

Learning to program

- Programming is a **skill** which can be learnt, but **not taught**.
- Many levels of your brain need to be trained to work together:
 - Solve **complex** tasks combining very **simple** operations
 - Pay attention to **tiny details** obvious to humans but not to computers.
 - Understanding of **existing** algorithms.
 - **Combine** simpler algorithms into bigger ones.
- Similarly to riding a bicycle, reading music, or speaking a foreign language, the only way of learning to program is **by doing**. And **practicing**. **A lot**.

Learning to program

Correlation plot of number of solved exercises vs course grade

<u>#Exercises</u>	<u>Success rate</u>	<u>Avg. Grade</u>
<70	8%	1,4
70-140	35%	3,9
140-200	71%	5,7
>200	93%	7,0

Correlation: 0,73

Python

- Python is an flexible and widely used programming language, allowing
 - **Scripting** (disposable small on-place code fragments for simple tasks)
 - **Structured** and **object-oriented** programming
 - Some **functional** programming
 - Allows interactive use:
REPL interpreter – **R**ead-**E**valuate-**P**rint **L**oop

Python program example (1)

```
from yogi import scan

# Ask the user her name and greet her
print("I am a python program, what is your name ?")
name = scan(str)
print(f"Hello {name}, nice to meet you.")
```

Python program example (2)

```
from yogi import scan

# Ask the user to input 2 numbers, then
# do some computations with them
print("Please, enter 2 numbers")
x = scan(int)
y = scan(int)
s = x + y
p = x * y
print("The sum of", x, "and", y, "is", s)
print("and their product is", p)
```

Python program example (3)

```
from yogi import scan

# Ask the user to input 1 numbers, then
# print a short multiplication table
print("Please, enter a number")
n = scan(int)
print(n, "x 1 =", n*1)
print(n, "x 2 =", n*2)
print(n, "x 3 =", n*3)
print(n, "x 4 =", n*4)
print(n, "x 5 =", n*5)
```

Python programs vs REPL

- A Python program is written in a **text file**, with extension **.py**, which can be executed by the interpreter

```
from yogi import scan
# Ask the user to input 2 numbers
print("Please, enter 2 numbers")
x = scan(int)
y = scan(int)
# do some computations with the numbers given by the user
s = x + y
p = x * y
# print results to the display for the user to see
print("The sum of", x, "and", y, "is", s)
print("and their product is", p)
```

Myprogram.py

```
$ python3 Myprogram.py
Please, enter 2 numbers
4 6
The sum of 4 and 6 is 10
and their product is 24
$
```

prompt

User
input

Python programs and REPL

- Python can also be used as a command line instruction interpreter. In this mode, the interpreter follows the **Read-Evaluate-Print Loop (REPL)**
 - The interpreter **reads** an instruction/expression from the user.
 - The interpreter **evaluates** the instruction/expression.
 - If the instruction/expression yields a value, it is **printed**.
 - The above steps are repeated in a **loop**.

Running python programs

- Computer processors do not understand **high level** programming languages (Java, Python, C++, etc), which are designed to be closer to humans.
- To be run in a computer, programs need to be in **executable** (a.k.a. *binary*) form.
- Python is an **interpreted** language, which means that there is a program (the python interpreter) that reads the code and tells the processor what to do.

Running python programs

- Once the program is written, we have to check whether it works as expected, comparing the actual output with what we intended to do

Linux

Linux desktop and command line

- In **Linux**, you have a desktop similar to that of any other O.S.
- Most tasks (**copying** or **renaming** a file, **moving** it to a different folder, **create** a new folder, etc) can be performed using the **graphical** desktop interface
- However, we are going to write **command-line** interface programs, which need to be run in a command line interpreter (also known as **console**, **terminal**, or **shell**)
- From the console, you can run commands to **execute** any program, or to **handle** files (copy, rename, move, etc).

Basic shell commands

- A terminal has, in a given moment, one and only one **current working directory** (i.e. the **folder** we have currently open).
- Shell commands are always referred to the current working directory

<code>cd <i>dirname</i></code>	Open folder called <i>dirname</i>
<code>cd ..</code>	Close current folder and go up to parent
<code>pwd</code>	Print current working directory
<code>ls</code>	List contents of current directory
<code>mkdir <i>dirname</i></code>	Create a new folder named <i>dirname</i>
<code>rmdir <i>dirname</i></code>	Remove folder <i>dirname</i>
<code>cp <i>file file2</i></code>	Copy <i>file1</i> to <i>file2</i>
<code>mv <i>file1 file2</i></code>	Rename <i>file1</i> to <i>file2</i>
<code>rm <i>file1</i></code>	Remove <i>file1</i>
<code>more <i>file1</i></code>	Show content of <i>file1</i>

Extensive and detailed step-by-step tutorial on shell commands for newbies:
<http://linuxcommand.org/>

Writing programs

Setting up programming environment

- Programs must be written on a **plain text** editor
- Linux offers several of them (emacs, kwrite, TextEditor, ...)
- We recommend **thonny**, already available in the provided OpenSuse virtual machine.

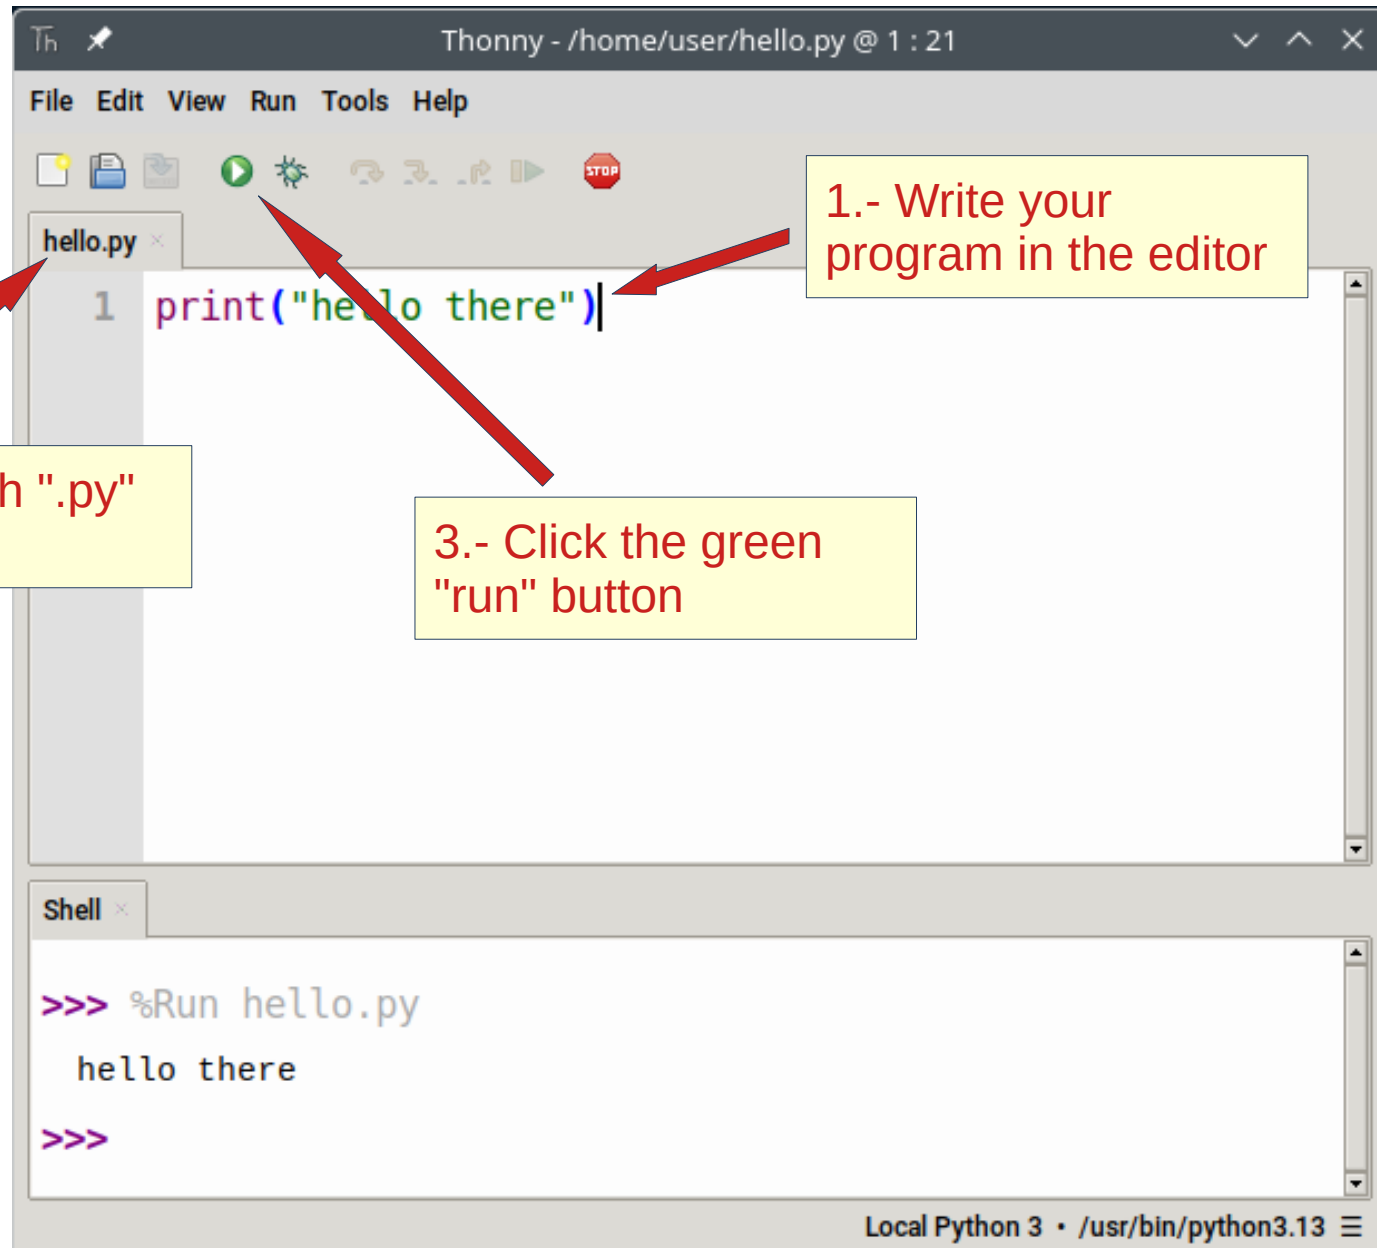

Writing a program

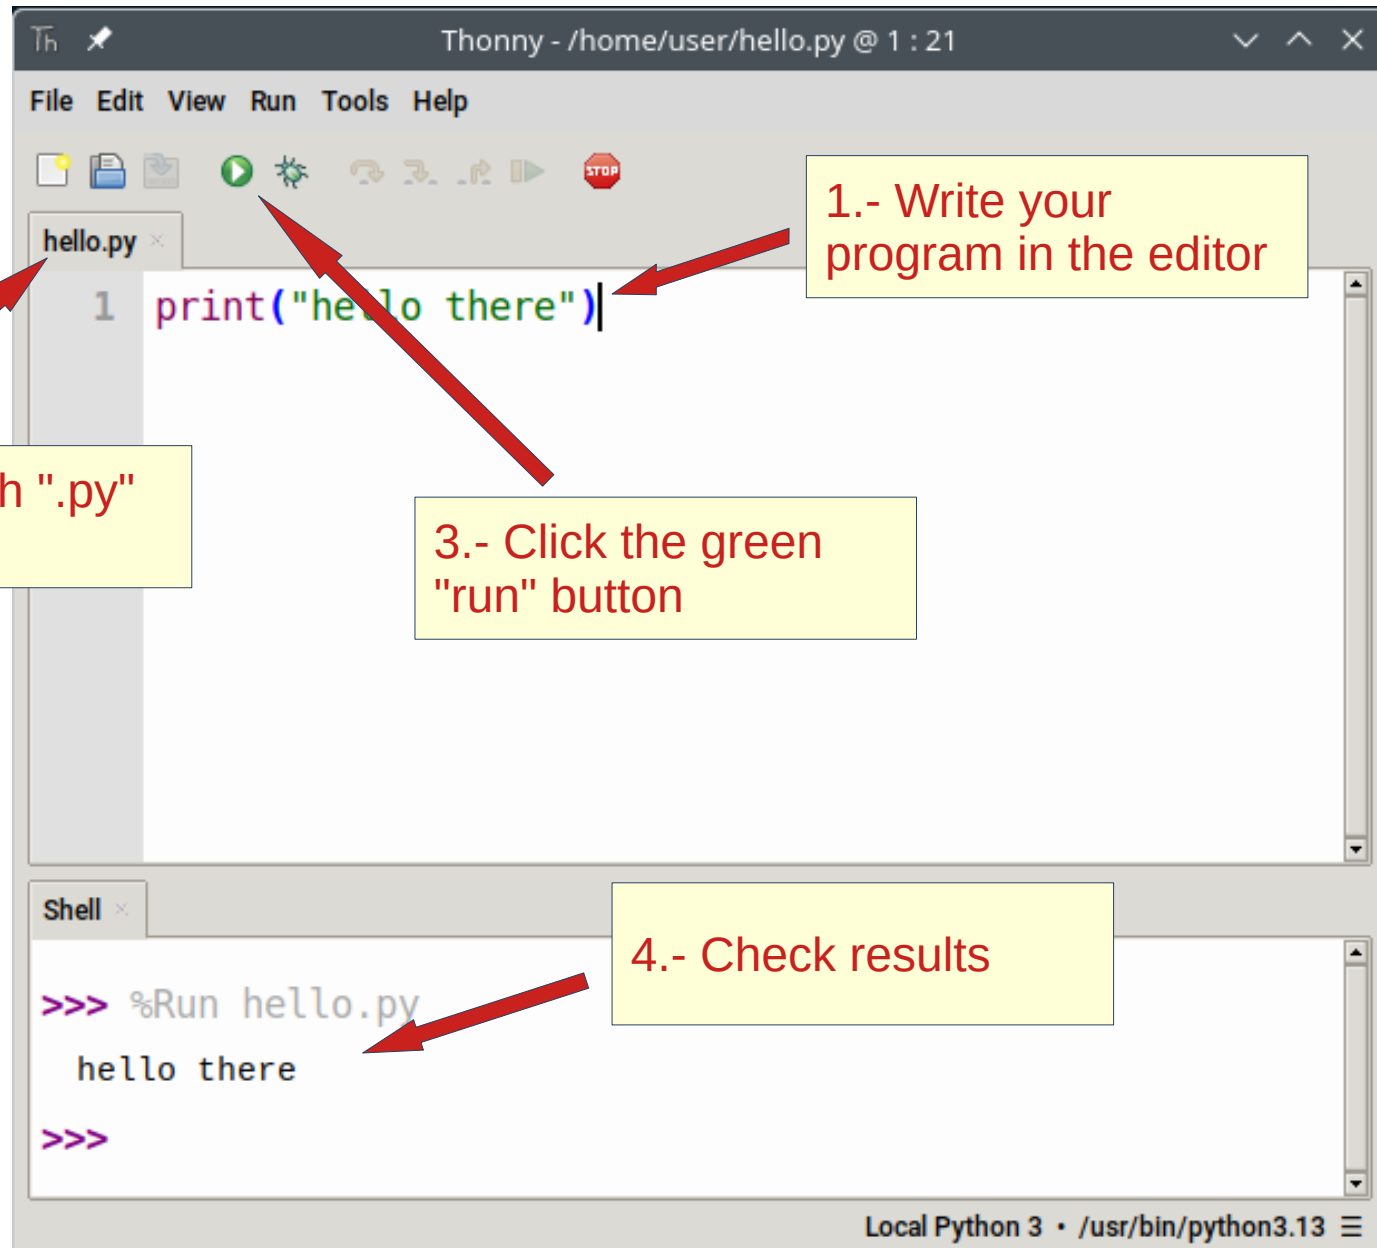

Writing a program

Writing a program

Writing a program

Thonny

- Thonny also allows to run your program in a terminal, so you can type any input.
- Thonny includes a useful *debugger* which will allow you to follow the steps of your program and find errors-

Details to come in Lab sessions

Organize your work

Organize you exercises

- During the course there will be two lab **exams**.
- There are **dozens** of exercises in the course lab.
- Exercises are organized in **lists**, by course chapters.
- Solving more exercises means better practice, and better preparation to face the exams
- It is crucial to have exercises **organized** to avoid getting lost.

Organize you exercises

- We recommend having a folder for each problem.
- It is also useful to group problem folders depending on the list they belong to.
- In each problem folder, you can have the statement, the python program, and its input and output files.

The *Jutge*

Automatic scoring of programs

- <https://jutge.org> is the environment where we will test the lab **exercises** and we will take the course **exams**.
- You have been invited to this course. Find it in the list, and click **“enroll this course”**.
- You can **submit** your programs to the jutge and find out whether they work.
- You can also **download** the input files and expected outputs for each problem, to check them in your PC.
