Abstract

A propositional proof system is automatizable if there is an algorithm that, given a tautology, produces a proof in time polynomial in the size of its smallest proof. This notion can be weakened if we allow the algorithm to produce a proof in a stronger system within the same time bound. This new notion is called weak automatizability. Among other characterizations, we prove that a system is weakly automatizable exactly when a weak form of the satisfiability problem is solvable in polynomial time. After studying the robustness of the definition, we prove the equivalence between: (i) Resolution is weakly automatizable, (ii) $\text{Res}(k)$ is weakly automatizable and (iii) $\text{Res}(k)$ has feasible interpolation, when $k > 1$. In order to prove this result, we show that $\text{Res}(2)$ has polynomial-size proofs of the reflection principle of Resolution, which is a version of consistency. We also show that $\text{Res}(k)$, for every $k > 1$, proves its consistency in polynomial size, while Resolution does not. In fact, we show that Resolution proofs of its own consistency require almost exponential size. This gives a better lower bound for the monotone interpolation of $\text{Res}(2)$ and a separation from Resolution as a byproduct. Our techniques also give us a way to obtain a large class of examples that have small Resolution refutations but require relatively large width. This answers a question of Alekhovich and Razborov related to whether Resolution is automatizable in quasipolynomial-time.

1 Introduction

Considerable effort has gone into studying algorithms for propositional satisfiability in several areas of computer science, despite the problem is NP-complete. The complementary problem of verifying propositional tautologies also received considerable attention, despite the fact that the problem is obviously also hard, namely co-NP-complete. As a consequence of the pioneering work of Cook and Reckhow [CR79], there is strong evidence that no propositional proof system P can prove every tautology in polynomial size. Thus, there is strong evidence that for no proof system P , there will be an algorithm that will produce P -proofs in time polynomial in the size of the tautology. This is because in some cases we might require super-polynomial time just to write down the proof.

Considering this limitation of proof systems, Bonet, Pitassi and Raz [BPR00] proposed the following definition. A propositional proof system P is *automatizable* if there exists an algorithm that, given a tautology, produces a P -proof of it in time polynomial in the size of its smallest P -proof. The idea is that if short P -proofs exist, an automatization algorithm for P should find them quickly. Somewhat surprisingly perhaps, this weaker notion turned out to be a strong requirement too for several natural systems. In the sequence of papers [KP98, BPR00, BDG⁺99] it was proved that no proof system that simulates bounded-depth Frege is automatizable, unless some widely accepted cryptographic conjecture is violated. Later, Alekhovich and Razborov [AR01] proved that Resolution is not automatizable under a reasonable assumption in parameterized complexity theory. The situation remains unknown for proof systems that lie between Resolution and bounded-depth Frege. In particular, it is open whether a proof system that simulates Resolution is automatizable.

In this paper we show the robustness of a notion that we call weak automatizability, and study in detail the particular case of Resolution. We say that a proof system P is *weakly automatizable* if there exists proof system Q and an algorithm that, given a tautology, produces a Q -proof of it in time polynomial in its smallest P -proof. In such a case we say that P is automatizable in terms of Q . Obviously, P is automatizable exactly when it is automatizable in terms of itself. Thus, our notion is a natural extension. In fact, we believe that weak automatizability might be more interesting from the point of view of applications. This is because usually we want to verify tautologies without restricting ourselves to having proofs in a particular system. But at the same time it is desirable to have the time of the proof search algorithm measured in terms of a proof system that we know a lot about (such as Resolution). We discuss the robustness of this new definition by providing several characterizations that we describe next. Let us fix a refutational proof system P and consider the following weak form of the satisfiability problem:

WEAK SAT for P

Input: A CNF formula F and a positive integer m .
Output: Return 1 if F is satisfiable, 0 if F has a P -refutation of size at most m , and anything in any other case.

Intuitively, an algorithm that solves this weak form of the satisfiability problem might provide a wrong answer, but only on those CNF formulas that require long refutations in P , for a bound m of our choice. Thus, if the unsatisfiable instances of our application have short refutations for some application-dependent reason, a fast algorithm for this problem is of practical importance. Our first

result is that P is weakly automatizable if and only if the problem *WEAK SAT* for P is solvable in time polynomial in m and the size of F .

As it turns out, the computational problem *WEAK SAT* for a system P is not new in the proof complexity literature. Pudlák [Pud01, Pud03], following the work of Razborov [Raz94], considered the problem of separating the canonical NP-pair of a proof system P by a polynomial-time algorithm. It is almost immediate from the definitions (see Section 2), that our problem is a reformulation of theirs. Moreover, Pudlák [Pud03] showed that the canonical NP-pair of P is polynomially separable if and only if there exists a proof system that simulates P and is automatizable. Summing up, all four concepts introduced so far are equivalent:

- (i) P is weakly automatizable,
- (ii) There is a proof system that simulates P and is automatizable,
- (iii) *WEAK SAT* for P is solvable in time polynomial in m and the size of F ,
- (iv) The canonical NP-pair of P is polynomially separable.

For automatizability, we also present an equivalent notion which is related to the problem of proof size approximation first considered in [ABMP01]. We provide details in Section 3.

Let us turn our attention to the particular case of Resolution. As pointed out already, it remains open whether a system that simulates Resolution can be automatizable. Thus, in view of our previous result, it remains open whether Resolution is weakly automatizable. In this paper we show that this question is equivalent to whether $\text{Res}(2)$ has feasible interpolation. In fact we show that the following are equivalent for every $k > 1$: (i) Resolution is weakly automatizable, (ii) $\text{Res}(k)$ is weakly automatizable and (iii) $\text{Res}(k)$ has feasible interpolation. The systems $\text{Res}(k)$ and the notion of feasible interpolation will be defined in Sections 4 and 2. Let us say for the moment, that Resolution, Cutting Planes, Relativized Bounded Arithmetic, Polynomial Calculus, Lovász-Schrijver, and Nullstellensatz all have feasible interpolation (see [IPU94, BPR97, Pud97, CH99, Kra97a, Raz95, PS98, Pud99]). On the other hand, the stronger system Frege, and any system that simulates bounded-depth Frege, do not have feasible interpolation under a cryptographic conjecture [KP98, BPR00, BDG⁺99].

To prove the three equivalences mentioned above we show that $\text{Res}(2)$ has polynomial-size proofs of the reflection principle of Resolution, which is a form of consistency saying that if a CNF formula is satisfiable, then it does not have a Resolution refutation. We extend this result by proving that $\text{Res}(k)$ has small proofs of its own consistency for $k > 1$. In contrast we show that Resolution requires almost exponential size to prove its own consistency. As a corollary we get an almost exponential lower bound for the monotone interpolation of $\text{Res}(2)$ improving over the quasipolynomial lower bound in [ABE02]. It also shows that $\text{Res}(2)$ is almost exponentially stronger than Resolution (recently [SBI02] proved a truly exponential separation).

These results promote the $\text{Res}(k)$ systems not only as proof systems of independent interest, but also as an important tool for studying the complexity of Resolution. As a matter of fact, our techniques strongly depend on the fact, first noted in this paper, that the proofs in the $\text{Res}(k)$ systems are in a sense translatable into Resolution and conversely. The precise results are stated in Section 4. We believe these techniques, although technically simple, will be useful in future work on the algorithmic aspects of Resolution.

Despite the discouraging results in [AR01] mentioned before, there is still some effort put into finding good algorithms for the proof search problem of Resolution. The first implementations were variants of the Davis-Putnam procedure [DP60, DLL62] for testing unsatisfiability which either produce a tree-like Resolution refutation (if one exists), or give a satisfying assignment. For various versions of this algorithm, one can prove that it is not an automatization procedure even for tree-like Resolution. A theoretically better algorithm for finding tree-like Resolution refutations was proposed by Beame and Pitassi [BP96]. They give an algorithm that works in time quasipolynomial in the size of the smallest tree-like refutation. So tree-like Resolution is automatizable in quasipolynomial time, but the algorithm is not a good automatization procedure for general Resolution (see [BEGJ00, BSIW02, BG01]). A more efficient algorithm is the one of Ben-Sasson and Wigderson based on the width of a refutation. This algorithm weakly automatizes tree-like Resolution in quasipolynomial time and automatizes Resolution in subexponential time. On the other hand, Bonet and Galesi [BG01] gave a class of tautologies for which the algorithm will take subexponential time to finish, matching the upper bound. Using the techniques introduced in this paper, we show that this is not an isolated example. We describe a method to produce tautologies that have small Resolution refutations but require relatively large width, answering an open problem of Alekhovich and Razborov [AR01]. As they claim, this is a necessary step towards proving that Resolution is not automatizable in quasipolynomial-time.

2 Automatizability, Interpolation, and Reflection Principles

We reserve the letter Σ possibly with subindices for finite alphabets. Let $TAUT$ be the set of propositional tautologies appropriately encoded in some finite alphabet. The following definitions are taken directly from Cook and Reckhow [CR79].

Definition 1 *A propositional proof system is a polynomial-time computable function $f : \Sigma^* \rightarrow TAUT$ that is onto. We say that the proof system is polynomially bounded if and only if there is a polynomial $p(n)$ such that for all $y \in TAUT$ there is $x \in \Sigma^*$ such that $y = f(x)$ and $|x| \leq p(|y|)$, where $|z|$ denotes the length of a string z . If $y = f(x)$, then we will say that x is an f -proof of y , and x is a short proof of y if in addition $|x| \leq p(|y|)$.*

Cook and Reckhow pointed out that $TAUT$ is in NP if and only if there exists a polynomially bounded proof system. They also introduced a concept that compares the relative power of proof systems. Here is their definition:

Definition 2 *Let f and g be propositional proof systems. We say that g simulates f if and only if there is a polynomial p such that for all x and y such that $f(x) = y$, there exists x' satisfying $|x'| \leq p(|x|)$ and $g(x') = y$.*

We turn next to the following more recent definitions. For a fixed proof system $f : \Sigma^* \rightarrow TAUT$, consider the problem of finding a proof $x \in \Sigma^*$ of a given $y \in TAUT$. Clearly, this problem is solvable in polynomial-time only if f is polynomially bounded, and in fact, only if $TAUT \in P$. A weaker requirement possibly of wider relevance might be that of solving the problem in time polynomial in the shortest f -proof of y . With this new requirement, a proof system might not be

polynomially bounded in general, but the problem of finding proofs might be solvable efficiently when short proofs exist. A proof system with this property is called *automatizable*. The concept was introduced by Bonet, Pitassi, and Raz [BPR00].

Definition 3 A proof system $f : \Sigma^* \rightarrow TAUT$ is *automatizable* if and only if there is a deterministic Turing machine M and a polynomial p such that for every $y \in TAUT$ it holds that $f(M(y)) = y$ and M on input y halts in time at most $p(|x|)$ where $x \in \Sigma^*$ is the shortest f -proof of y .

In some practical situations, the only relevant question is that of finding proofs in *some* proof system, not necessarily f itself. If proofs in another proof system can be found in time polynomial in the shortest f -proof, we say that f is *weakly automatizable*.

Definition 4 A proof system f is *weakly automatizable* if and only if there exists another proof system g , a deterministic Turing machine M , and a polynomial p such that for every $y \in TAUT$ it holds that $g(M(y)) = y$ and M on input y halts in time at most $p(|x|)$ where $x \in \Sigma^*$ is the shortest f -proof of y . In that case, we say that f is *automatizable in terms of g* .

Observe that if f is automatizable in terms of g , then g simulates f . After all, it could be that f is not automatizable but some proof system that simulates it is. Finally, we consider several related algorithmic problems with respect to a proof system f . The first problem that we consider is a separation problem, namely, that of distinguishing a $y \in TAUT$ with a proof of size at most m from a y that does not even belong to $TAUT$. This problem was introduced by Razborov [Raz95] (see also [Pud03]) under the name of the *separation problem for the canonical pair*.

Definition 5 The *canonical NP-pair* of a proof system f is the following pair of languages:

$$\begin{aligned} A_0^f &= \{\langle y, 1^m \rangle : y \in TAUT \text{ and } f(x) = y \text{ for some } x \in \Sigma^* \text{ such that } |x| \leq m\}, \\ A_1^f &= \{\langle y, 1^m \rangle : y \notin TAUT\}. \end{aligned}$$

Following Pudlák [Pud03], we say that a pair of disjoint languages $L_0 \cap L_1 = \emptyset$ is polynomially separable if there exists a polynomial-time computable function $h : \Sigma^* \rightarrow \{0, 1\}$ such that $h(L_0) \subseteq \{0\}$ and $h(L_1) \subseteq \{1\}$. That is, $h(x) = 0$ if $x \in L_0$, $h(x) = 1$ if $x \in L_1$, and $h(x)$ can be 0 or 1 elsewhere.

Observe that when considering refutational systems, such as Resolution, one works with the set of unsatisfiable CNF formulas, instead of $TAUT$. In such a case, the canonical NP-pair consists of the set of pairs $\langle F, 1^m \rangle$ where F is a CNF with refutations of size at most m , and the set of pairs $\langle F, 1^m \rangle$ where F is a satisfiable CNF. It is immediately seen that the canonical pair is polynomially separable if and only if the problem *WEAK SAT* for f defined in the introduction is solvable in time polynomial in m and the size of F .

The disjointness of the canonical NP-pair for a refutational proof system f is often expressible as a contradictory set of clauses. Suppose that $SAT_r^n(x, z)$ is a CNF formula meaning that “ z encodes a truth assignment that satisfies the CNF formula encoded by x .” Here, r is the number of clauses of the CNF formula encoded by x , and n is the number of underlying variables v_1, \dots, v_n . Similarly, suppose that $REF_{r,m}^n(x, y)$ is a CNF formula meaning that “ y encodes an f -refutation

of the CNF formula encoded by x ." Here, m is the size of the refutation encoded by y , and r and n are as before. Under these two assumptions, the disjointness of the canonical NP-pair for f is expressible by the contradictions

$$SAT_r^n(x, z) \wedge REF_{r,m}^n(x, y).$$

This collection of CNF formulas is known as the *reflection principle* of f . Notice that it is a form of consistency of f .

We define yet another separation problem, this time it is an NP/co-NP pair.

Definition 6 *The canonical NP/co-NP-pair of a proof system f and a polynomial p is the following pair of languages:*

$$\begin{aligned} A_0^{f,p} &= \{ \langle y, 1^m \rangle : f(x) = y \text{ for some } x \in \Sigma^* \text{ such that } |x| \leq m \}, \\ A_1^{f,p} &= \{ \langle y, 1^m \rangle : \text{for all } x \in \Sigma^*, f(x) = y \text{ implies } |x| > p(m) \}. \end{aligned}$$

Notice that the problem of separating the canonical NP/co-NP pair of a proof system, is equivalent to the problem of approximating minimal proof size within a polynomial.

We turn next to the concept of feasible interpolation introduced by Krajíček [Kra97a] (see also [BPR97, Pud97]). Suppose that $A_0(x, y_0) \wedge A_1(x, y_1)$ is a contradictory CNF formula, where x , y_0 , and y_1 are disjoint sets of variables. Note that for every given truth assignment a for the variables x , one of the formulas $A_0(a, y_0)$ or $A_1(a, y_1)$ must be contradictory by itself.

Definition 7 *A refutational proof system f has feasible interpolation if there exists a Turing machine M and a polynomial p that, given a refutation r of an unsatisfiable CNF formula $A_0(x, y_0) \wedge A_1(x, y_1)$ and given a truth assignment a for the common variables, M on input $\langle r, a \rangle$ halts in $p(|r|)$ steps and returns $i \in \{0, 1\}$ such that $A_i(a, y_i)$ is unsatisfiable.*

We note that this definition is a uniform version of feasible interpolation as defined in [BPR00, Kra97a, Pud97]. If in the definition we replace the Turing machine by a Boolean circuit we obtain the non-uniform version. Moreover, this allows us to define the monotone version of feasible interpolation. That is, a proof system has monotone feasible interpolation if the interpolating circuit is monotone in a when either $A_0(x, y_0)$ or $A_1(x, y_1)$ are such that the x -variables appear only positively or only negatively.

3 Robustness of the Definitions

The aim of this section is to show that the definitions of Section 2 lead to a nice theory. Our first result establishes an informative characterization of weak automatizability. We note that the equivalence between (ii) and (iii) was first noted by Pudlák [Pud01]. We reproduce it here for completeness:

Theorem 1 *If $f : \Sigma^* \rightarrow TAUT$ is a proof system, then the following are equivalent:*

- (i) f is weakly automatizable,

- (ii) *There is a proof system g that simulates f and is automatizable,*
- (iii) *The canonical NP-pair of f is polynomially separable,*

Proof: We close a cycle of implications (iii) implies (ii), (ii) implies (i), and (i) implies (iii).

(iii) implies (ii) [Pud01]. Suppose that the canonical NP-pair of f is polynomially separated by h . Let Σ_1 be a finite alphabet that is suitable to encode pairs of the form $\langle y, 1^m \rangle$. Let $g : \Sigma_1^* \rightarrow TAUT$ be the following proof system. If $w \in \Sigma_1^*$ encodes a pair of the form $\langle y, 1^m \rangle$ and $h(\langle y, 1^m \rangle) = 0$, then $g(w) = y$. Otherwise $g(w) = p \vee \neg p$. We show that g simulates f . Indeed, if x is an f -proof, then $\langle f(x), 1^{|x|} \rangle$ is a g -proof of the same formula. We also show that g is automatizable. The algorithm is as follows: given y , find by binary search the minimal m such that $h(\langle y, 1^m \rangle) = 0$, and output $\langle y, 1^m \rangle$. Such an m must exist and the running time is polynomial in the length of $\langle y, 1^m \rangle$.

(ii) implies (i). Suppose that $g : \Sigma_2^* \rightarrow TAUT$ is an automatizable proof system that simulates f . For every $x \in \Sigma^*$, let $h(x)$ be the shortest g -proof of $f(x)$. Let q be a polynomial such that $|h(x)| \leq q(|x|)$. Such a polynomial exists because g simulates f . Let M and p be the Turing machine and the polynomial that witness the fact that g is automatizable. We may assume that p is a monotone non-decreasing function of its argument. We claim that the same machine M and the polynomial $p(q(n))$ witness the fact that f is automatizable in terms of g . To see this, suppose that $y \in TAUT$. Let $x \in \Sigma^*$ be the shortest f -proof of y and let $x' = h(x)$. Observe that $|x'| \leq q(|x|)$. Moreover, M on input y halts in at most $p(|x'|) \leq p(q(|x|))$ steps and its output x'' is such that $g(x'') = y$. This shows that f is weakly automatizable.

(i) implies (iii). Suppose that f is weakly automatizable. Let $g : \Sigma_2^* \rightarrow L$ be the proof system in terms of which f is automatizable. Let M and p be a Turing machine witnessing it. Let N be the Turing machine that behaves as follows. On input $\langle y, 1^m \rangle$, it simulates M on input y for $p(m)$ steps. If M halted and the output is such that $g(M(y)) = y$, then it outputs 0. In any other case, it outputs 1. We claim that N witnesses the fact that A_0^f and A_1^f are polynomially separable. Clearly, N runs in polynomial-time. Suppose now that y has an f -proof of length at most m . Then M on input y halts in at most $p(m)$ steps and outputs some x such that $g(x) = y$. It follows that N outputs 0 on $\langle y, 1^m \rangle$. On the other hand, if $y \notin TAUT$, then there is no x for which $g(x) = y$. It follows that N outputs 1 on $\langle y, 1^m \rangle$. \square

We turn next to a similar characterization of automatizability in terms of canonical pairs. Recall that two systems are equivalent if they simulate each other.

Theorem 2 *If $f : \Sigma^* \rightarrow TAUT$ is a proof system, then the following are equivalent:*

- (i) *There is a proof system equivalent to f that is automatizable,*
- (ii) *The canonical NP/co-NP-pair of f and some polynomial is polynomially separable.*

Proof: We prove both implications (i) implies (ii) and (ii) implies (i).

(i) implies (ii). Let g be the automatizable proof system that is polynomially equivalent to f . Let M be the automatization algorithm, and q the time in which M works. Given that f and g are polynomially equivalent, there are two polynomials p' and p'' , such that if $f(x) = y$, there exists x' satisfying $|x'| \leq p'(|x|)$ and $g(x') = y$, and if $g(x) = y$, there exists x' satisfying $|x'| \leq p''(|x|)$ and $f(x') = y$. Now we need to choose a polynomial p such that $p''^{(-1)}(p(m)) > q(p'(m))$ (if $p'' = n^c$

then $p^{n^{(-1)}} = n^{1/c}$. Now we will show that the canonical NP/co-NP pair for the polynomial p and the system f is separable. On input $\langle y, 1^m \rangle$, run M on y for $q(p'(m))$ steps. If the algorithm M returns a proof, return 0, and otherwise 1.

If y has an f -proof of size at most m , then y has a g -proof of size at most $p'(m)$, and the algorithm will find a proof in time $q(p'(m))$. On the other hand, if y doesn't have an f -proof of size at most $p(m)$, then g doesn't have a proof of y of size at most $p^{n^{(-1)}}(p(m))$. In this case, given that $p^{n^{(-1)}}(p(m)) > q(p'(m))$, the algorithm will not return a proof, and the output will be 1.

(ii) implies (i). Suppose that the canonical NP/co-NP-pair of f for some polynomial p is polynomially separated by the function h . We define the propositional proof system g as in part (iii) implies (ii) of the previous theorem. We show there that g is an automatizable propositional proof system that simulates f . Now we will also show that f simulates g . If $g(x) = y \neq p \vee \neg p$, by definition $x = \langle y, 1^m \rangle$ and $h(\langle y, 1^m \rangle) = 0$. Then there is x' such that $f(x') = y$ and $|x'| \leq p(m)$ (otherwise $h(\langle y, 1^m \rangle)$ would be 1). If $g(x) = p \vee \neg p$, then construct a small f -proof of $p \vee \neg p$. \square

We close this section by recalling the known relationship between the concepts of feasible interpolation, automatizability, and reflection principles. First, let us define the following mild condition on a proof system f . We say f is projection-closed if, whenever $A(x)$ has an f -proof of size m , any restriction of $A(x)$ by a partial truth assignment on x has an f -proof of size at most polynomial in m . We note that most natural proof systems are projection-closed, and that the definition applies as well to refutational systems.

Theorem 3 ([BPR00]) *Let f be a refutational proof system that is projection-closed. If f is automatizable or weakly automatizable, then f has feasible interpolation.*

In fact, in [BPR00], this result is stated and proved for f automatizable. We note that a similar proof works for f weakly automatizable.

The following is a partial converse:

Theorem 4 ([Pud03]) *If the reflection principle of f has polynomial-size refutations in a proof system that has feasible interpolation, and the refutations are given uniformly in polynomial-time, then f is weakly automatizable.*

4 Resolution Based Propositional Proof Systems

Resolution is a refutational proof system for CNF formulas, that is, conjunctions of clauses. The system has one inference rule, the *resolution rule*:

$$\frac{A \vee x \quad B \vee \neg x}{A \vee B}$$

where x is a variable, and A and B are clauses. The refutation finishes with the empty clause. The *size* of a Resolution refutation is the number of clauses in it. The system *tree-like Resolution* requires that each occurrence of a clause is used at most once. When this restriction is not fulfilled, we say that the refutation is in *DAG* form.

A k -term is a conjunction of up to k literals. A k -disjunction is an (unbounded fan-in) disjunction of k -terms. The refutation system $\text{Res}(k)$, defined by Krajíček [Kra01], works with k -disjunctions. There are three inference rules in $\text{Res}(k)$: Weakening, \wedge -Introduction, and Cut.

$$\frac{A}{A \vee B} \quad \frac{A \vee l_1 \quad B \vee (l_2 \wedge \dots \wedge l_s)}{A \vee B \vee (l_1 \wedge \dots \wedge l_s)} \quad \frac{A \vee (l_1 \wedge \dots \wedge l_s) \quad B \vee \neg l_1 \vee \dots \vee \neg l_s}{A \vee B}$$

Here A and B are k -disjunctions, the l_i 's are literals, and $s \leq k$. We also allow the axioms $x \vee \neg x$. Observe that $\text{Res}(1)$ is equivalent to Resolution since the axioms and the weakening rule are easy to eliminate in this case. The size of a $\text{Res}(k)$ refutation is the number of k -disjunctions in it. As in Resolution, the tree-like version of $\text{Res}(k)$ requires each occurrence of a k -disjunction to be used only once.

For every set of literals l_1, \dots, l_s we define a new variable $z(l_1, \dots, l_s)$ meaning $l_1 \wedge \dots \wedge l_s$. The following clauses define $z(l_1, \dots, l_s)$:

$$\begin{aligned} &\neg z(l_1, \dots, l_s) \vee l_i \text{ for every } i \in \{1, \dots, s\} \\ &\neg l_1 \vee \dots \vee \neg l_s \vee z(l_1, \dots, l_s) \end{aligned}$$

Let F be a CNF formula on the variables x_1, \dots, x_n . For every integer $k > 0$, we define $F(k)$ as the conjunction of F with all the defining clauses for the variables $z(l_1, \dots, l_s)$ for all $s \leq k$.

Lemma 1 *If F has a $\text{Res}(k)$ refutation of size S , then $F(k)$ has a Resolution refutation of size $O(kS)$. Furthermore, if the $\text{Res}(k)$ refutation is tree-like, then the Resolution refutation is also tree-like.*

Proof: Let Π be a $\text{Res}(k)$ refutation of size S . To get a Resolution refutation of $F(k)$, we will first get a clause for each k -disjunction of Π . The translation consists in replacing each conjunction $l_1 \wedge \dots \wedge l_s$ for $s \leq k$ in a k -disjunction of Π by $z(l_1, \dots, l_s)$. Also we have to make sure that we can make this new sequence of clauses into a Resolution refutation so that if Π is tree-like, then the new refutation will also be. We have the following cases:

Case 1: In Π we have the step:

$$\frac{C \vee (l_1 \wedge \dots \wedge l_s) \quad D \vee \neg l_1 \vee \dots \vee \neg l_s}{C \vee D}$$

The corresponding clauses in the translation will be: $C' \vee z(l_1, \dots, l_s)$, $D' \vee \neg l_1 \vee \dots \vee \neg l_s$ and $C' \vee D'$. To get a tree-like proof of $C' \vee D'$ from the two other ones, first obtain $\neg z(l_1, \dots, l_s) \vee D'$ in a tree-like way from $D' \vee \neg l_1 \vee \dots \vee \neg l_s$ and the clauses $\neg z(l_1, \dots, l_s) \vee l_i$. Finally resolve $\neg z(l_1, \dots, l_s) \vee D'$ with $C' \vee z(l_1, \dots, l_s)$ to get $C' \vee D'$.

Case 2: In Π we have the step:

$$\frac{C \vee l_1 \quad D \vee (l_2 \wedge \dots \wedge l_s)}{C \vee D \vee (l_1 \wedge \dots \wedge l_s)}$$

The corresponding clauses in the translation will be: $C' \vee l_1$, $D' \vee z(l_2, \dots, l_s)$ and $C' \vee D' \vee z(l_1, \dots, l_s)$. Notice that there is a tree-like proof of $\neg l_1 \vee \neg z(l_2, \dots, l_s) \vee z(l_1, \dots, l_s)$ from the clauses of $F(k)$. Using this clause and the translation of the premises, we get $C' \vee D' \vee z(l_1, \dots, l_s)$.

Case 3: The Weakening rule turns into a weakening rule for Resolution which can be eliminated easily.

At this point we have obtained a Resolution refutation of $F(k)$ that may use axioms of the type $x \vee \neg x$. These can be eliminated easily too. \square

Lemma 2 *If $F(k)$ has a Resolution refutation of size S , then F has a $\text{Res}(k)$ refutation of size $O(kS)$. Furthermore, if the Resolution refutation is tree-like, then the $\text{Res}(k)$ refutation is also tree-like.*

Proof: We first substitute each clause of the Resolution refutation by a k -disjunction by translating $z(l_1, \dots, l_s)$ into $l_1 \wedge \dots \wedge l_s$ and $\neg z(l_1, \dots, l_s)$ into $\neg l_1 \vee \dots \vee \neg l_s$. At this point the rules of the Resolution refutation turn into valid rules of $\text{Res}(k)$.

Now we only need to produce proofs of the defining clauses of the z variables in $\text{Res}(k)$ to finish the simulation. The clauses $\neg z(l_1, \dots, l_s) \vee l_i$ get translated into $\neg l_1 \vee \dots \vee \neg l_s \vee l_i$, which is a weakening of the axiom $l_i \vee \neg l_i$. The clause $\neg l_1 \vee \dots \vee \neg l_s \vee z(l_1, \dots, l_s)$ gets translated into $\neg l_1 \vee \dots \vee \neg l_s \vee (l_1 \wedge \dots \wedge l_s)$ which can be proved from the axioms $l_i \vee \neg l_i$ using the rule for the introduction of \wedge . \square

5 Resolution: Reflection Principle and Weak Automatizability

In this section we establish the equivalence between: (i) Resolution is weakly automatizable, (ii) $\text{Res}(k)$ is weakly automatizable and (iii) $\text{Res}(k)$ has feasible interpolation, when $k > 1$. In the course of the proof we need to study the provability of the reflection principle of Resolution.

In what follows we will need a concrete encoding of the reflection principle. We start with the encoding of $\text{SAT}_r^n(x, z)$. The encoding of the set of clauses by the variables in x is as follows. There are variables $x_{e,i,j}$ for every $e \in \{0, 1\}$, $i \in \{1, \dots, n\}$ and $j \in \{1, \dots, r\}$. The meaning of $x_{0,i,j}$ is that the literal v_i appears in clause j , while the meaning of $x_{1,i,j}$ is that the literal $\neg v_i$ appears in clause j .

The encoding of the truth assignment $a \in \{0, 1\}^n$ by the variables z is as follows. There are variables z_i for every $i \in \{1, \dots, n\}$, and $z_{e,i,j}$ for every $e \in \{0, 1\}$, $i \in \{1, \dots, n\}$ and $j \in \{1, \dots, r\}$. The meaning of z_i is that variable v_i is assigned true under the truth assignment. The meaning of $z_{0,i,j}$ is that clause j is satisfied by the literal v_i , and the meaning of $z_{1,i,j}$ is that clause j is satisfied by the literal $\neg v_i$. Here is the set of clauses that formalizes $\text{SAT}_r^n(x, z)$:

$$\begin{aligned} z_{0,1,j} \vee z_{1,1,j} \vee \dots \vee z_{0,n,j} \vee z_{1,n,j} & \quad (1) & \neg z_{0,i,j} \vee z_i & \quad (2) \\ \neg z_{e,i,j} \vee x_{e,i,j} & \quad (3) & \neg z_{1,i,j} \vee \neg z_i & \quad (4) \end{aligned}$$

The meaning of clause (1) is that at least one literal is chosen to be satisfied in clause j . The meaning of clauses (2) and (4) ensure the consistency of this choice between clauses. The meaning of clause (3) is that if some literal satisfies clause j , then it appears in the clause.

The encoding of $\text{REF}_{r,m}^n(x, y)$ is quite standard. The encoding of the set of clauses by the variables in x is as before. The encoding of the Resolution refutation by the variables in y is as follows. There are variables $y_{e,i,j}$ for every $e \in \{0, 1\}$, $i \in \{1, \dots, n\}$, and $j \in \{1, \dots, m\}$. The meaning of $y_{0,i,j}$ is that the literal v_i appears in clause j of the refutation. Similarly, the meaning of $y_{1,i,j}$ is that the literal $\neg v_i$ appears in clause j of the refutation. There are variables

$p_{j,k}$ and $q_{j,k}$ for every $j \in \{1, \dots, m\}$ and $k \in \{r, \dots, m\}$. The meaning of $p_{j,k}$ (of $q_{j',k}$) is that clause C_k is obtained from clause C_j (from clause $C_{j'}$), and C_j contains the resolved variable positively ($C_{j'}$ contains it negatively). Finally, there are variables $w_{i,k}$ for every $i \in \{1, \dots, n\}$ and $k \in \{r, \dots, m\}$. The meaning of $w_{i,k}$ is that clause C_k is obtained by resolving upon v_i . We formalize this by the following set of clauses:

$$\begin{array}{ll}
\neg x_{e,i,j} \vee y_{e,i,j} & (5) \\
\neg y_{0,i,j} \vee \neg y_{1,i,j} & (7) \\
q_{1,k} \vee \dots \vee q_{k-1,k} & (9) \\
\neg p_{j,k} \vee \neg p_{j',k} & (11) \\
\neg p_{j,k} \vee \neg w_{i,k} \vee y_{0,i,j} & (13) \\
\neg p_{j,k} \vee w_{i,k} \vee \neg y_{e,i,j} \vee y_{e,i,k} & (15) \\
w_{1,k} \vee \dots \vee w_{n,k} & (17) \\
\neg y_{e,i,m} & (6) \\
p_{1,k} \vee \dots \vee p_{k-1,k} & (8) \\
\neg p_{j,k} \vee \neg q_{j,k} & (10) \\
\neg q_{j,k} \vee \neg q_{j',k} & (12) \\
\neg q_{j,k} \vee \neg w_{i,k} \vee y_{1,i,j} & (14) \\
\neg q_{j,k} \vee w_{i,k} \vee \neg y_{e,i,j} \vee y_{e,i,k} & (16) \\
\neg w_{i,k} \vee \neg w_{i',k} & (18)
\end{array}$$

The index j' ranges over $\{1, \dots, m\}$ with $j' \neq j$, and the index i' ranges over $\{1, \dots, n\}$ with $i' \neq i$. The meaning of clause (5) is that the initial clauses of the refutation are those of the formula. The meaning of clause (6) is that the last clause of the refutation is empty. The meaning of clause (7) is that the clauses of the refutation are not tautologies. Clauses (8) and (9) indicate that clause C_k is obtained from two previous clauses, one with the resolved variable positive and the other negative. Clauses (10), (11) and (12) ensure the structure of the resolution rule. Clauses (13) and (14) express that if a clause C_k is obtained from C_j by resolving on variable v_i (or $\neg v_i$), then v_i (or $\neg v_i$) appears in C_j . Clauses (15) and (16) express that after applying the rule, the non-resolved literals stay. Finally, clauses (17) and (18) say that C_k is obtained by resolving exactly one variable.

Notice that this encoding has the appropriate form of the monotone feasible interpolation because the x -variables appear only positively in $SAT_r^n(x, z)$ and in fact, only negatively in $REF_{r,m}^n(x, y)$ too. This will be of use later.

Theorem 5 *The reflection principle for Resolution, $SAT_r^n(x, z) \wedge REF_{r,m}^n(x, y)$, has Res(2) refutations of size $(nr + nm)^{O(1)}$.*

Proof: The goal is to get the following 2-disjunction

$$D_k \equiv \bigvee_{i=1}^n (y_{0,i,k} \wedge z_i) \vee (y_{1,i,k} \wedge \neg z_i)$$

for every $k \in \{1, \dots, m\}$. The empty clause will follow by resolving D_m with (6). We distinguish two cases: $k \leq r$ and $r < k \leq m$. Since the case $k \leq r$ is easier, we leave it to the reader.

For the case $r < k \leq m$, we show how to derive D_k from D_1, \dots, D_{k-1} . First, we derive $\neg p_{j,k} \vee \neg q_{l,k} \vee D_k$. From (14) and (7) we get $\neg q_{l,k} \vee \neg w_{q,k} \vee \neg y_{0,q,l}$. Resolving with D_l on $y_{0,q,l}$ we get

$$\neg q_{l,k} \vee \neg w_{q,k} \vee (y_{1,q,l} \wedge \neg z_q) \vee \bigvee_{\substack{i=1 \\ i \neq q}}^n (y_{0,i,l} \wedge z_i) \vee (y_{1,i,l} \wedge \neg z_i). \quad (19)$$

A cut with $z_q \vee \neg z_q$ on $y_{1,q,l} \wedge \neg z_q$ gives

$$\neg q_{l,k} \vee \neg w_{q,k} \vee \neg z_q \vee \bigvee_{\substack{i=1 \\ i \neq q}}^n (y_{0,i,l} \wedge z_i) \vee (y_{1,i,l} \wedge \neg z_i). \quad (20)$$

Let $q' \neq q$. A cut with $z_{q'} \vee \neg z_{q'}$ on $y_{0,q',l} \wedge z_{q'}$ gives

$$\neg q_{l,k} \vee \neg w_{q,k} \vee \neg z_q \vee z_{q'} \vee (y_{1,q',l} \wedge \neg z_{q'}) \vee \bigvee_{i \neq q, q'} (y_{0,i,l} \wedge z_i) \vee (y_{1,i,l} \wedge \neg z_i). \quad (21)$$

From (16) and (18) we get $\neg q_{l,k} \vee \neg w_{q,k} \vee \neg y_{0,q',l} \vee y_{0,q',k}$. Resolving with (20) on $y_{0,q',l} \wedge z_{q'}$ gives

$$\neg q_{l,k} \vee \neg w_{q,k} \vee \neg z_q \vee y_{0,q',k} \vee (y_{1,q',l} \wedge \neg z_{q'}) \vee \bigvee_{i \neq q, q'} (y_{0,i,l} \wedge z_i) \vee (y_{1,i,l} \wedge \neg z_i). \quad (22)$$

An introduction of conjunction between (21) and (22) gives

$$\neg q_{l,k} \vee \neg w_{q,k} \vee \neg z_q \vee (y_{0,q',k} \wedge z_{q'}) \vee (y_{1,q',l} \wedge \neg z_{q'}) \vee \bigvee_{i \neq q, q'} (y_{0,i,l} \wedge z_i) \vee (y_{1,i,l} \wedge \neg z_i). \quad (23)$$

From (16) and (18) we also get $\neg q_{l,k} \vee \neg w_{q,k} \vee \neg y_{1,q',l} \vee y_{1,q',k}$. Repeating the same procedure we get

$$\neg q_{l,k} \vee \neg w_{q,k} \vee \neg z_q \vee (y_{0,q',k} \wedge z_{q'}) \vee (y_{1,q',k} \wedge \neg z_{q'}) \vee \bigvee_{i \neq q, q'} (y_{0,i,l} \wedge z_i) \vee (y_{1,i,l} \wedge \neg z_i). \quad (24)$$

Now, repeating this two-step procedure for every $q' \neq q$, we get

$$\neg q_{l,k} \vee \neg w_{q,k} \vee \neg z_q \vee \bigvee_{i \neq q} (y_{0,i,k} \wedge z_i) \vee (y_{1,i,k} \wedge \neg z_i). \quad (25)$$

A dual argument would yield $\neg p_{j,k} \vee \neg w_{q,k} \vee z_q \vee \bigvee_{i \neq q} (y_{0,i,k} \wedge z_i) \vee (y_{1,i,k} \wedge \neg z_i)$. A cut with (25) on z_q gives $\neg p_{j,k} \vee \neg q_{l,k} \vee \neg w_{q,k} \vee \bigvee_{i \neq q} (y_{0,i,k} \wedge z_i) \vee (y_{1,i,k} \wedge \neg z_i)$. Weakening gives then $\neg p_{j,k} \vee \neg q_{l,k} \vee \neg w_{q,k} \vee D_k$. Since the indices j , l , and q were arbitrary, we obtain the same formula for every such triple. Using (17) gives $\neg p_{j,k} \vee \neg q_{l,k} \vee D_k$, again for every pair of indices j and l . To complete the proof, we use this with (8) to get $\neg q_{l,k} \vee D_k$ for every l , and then (9) to get D_k .

For the size of the refutation, we consider both cases $k \leq r$ and $k > r$. There are r initial clauses and each corresponding D_k has size $O(n)$. Deriving all of these takes size $(nr)^{O(1)}$. The rest of D_k 's also have size $O(n)$ and there are $m - r$ of these. Deriving D_{k+1} from D_1, \dots, D_k takes size $(nm)^{O(1)}$ because C_{k+1} can be derived from any pair of previous clauses. Overall, this is size $(nr + nm)^{O(1)}$. \square

The previous theorem can be generalized to reflection principles for $\text{Res}(k)$. This requires a modification of $REF_{r,m}^n(x, y)$ to refutations in $\text{Res}(k)$. For Resolution, the refutation was encoded by the variables $y_{e,i,j}$ meaning that the variable v_i appears in clause j positively or negatively. Now we need variables $y_{e_1, i_1, \dots, e_l, i_l, j}$ for $l \in \{1, \dots, k\}$, $e_1, \dots, e_l \in \{0, 1\}$, $i_1, \dots, i_l \in \{1, \dots, n\}$, and $j \in \{1, \dots, m\}$. Their meaning is that the k -disjunction C_j contains the term $v_{i_1}^{(e_1)} \wedge \dots \wedge v_{i_l}^{(e_l)}$, where $v_i^{(0)}$ is v_i and $v_i^{(1)}$ is $\neg v_i$. The structure of the refutation is encoded by variables t , p , q , and w . The variables $t_{1,j}, \dots, t_{4,j}$ for $j \in \{1, \dots, m\}$ specify whether C_j is obtained by weakening, introduction of conjunction, cut, or is an axiom respectively. The variables $p_{j,j'}$ ($q_{j,j'}$) for $j, j' \in \{1, \dots, m\}$ indicate that the left (right) hypothesis of $C_{j'}$ is C_j . The variables $w_{e_1, i_1, \dots, e_l, i_l, j}$ have different meanings depending on the rule. If C_j is obtained by cut, it means that the resolved term is $v_{i_1}^{(e_1)} \wedge \dots \wedge v_{i_l}^{(e_l)}$. If C_j is obtained by introduction of conjunction, it means that the introduced

conjunction is $v_{i_1}^{(e_1)} \wedge \dots \wedge v_{i_l}^{(e_l)}$. Notice that the rule has a fixed format, namely, the first literal is in the left hypothesis, and the conjunction of the rest is in the right hypothesis. If C_j is an axiom, it specifies which variable is in the axiom and $l = 1$ in this case. If C_j is obtained by weakening, the values of w are irrelevant. Writing the set of clauses expressing this is straightforward. We only give an example of one of the new clauses. The clause

$$\neg t_{2,j'} \vee \neg p_{j,j'} \vee \neg w_{e_1,i_1,\dots,e_l,i_l,j'} \vee y_{e_1,i_1,j}$$

means that if $C_{j'}$ is obtained by introduction of conjunction with C_j as left hypothesis, and the introduced conjunction is $v_{i_1}^{(e_1)} \wedge \dots \wedge v_{i_l}^{(e_l)}$, then the literal $v_{i_1}^{(e_1)}$ appears in $C_{j'}$.

The resulting set of clauses is called $REF_{r,m}^{n,k}(x, y)$. Notice the new superindex k in REF to indicate that the refutation is in $\text{Res}(k)$.

Theorem 6 *The reflection principle for $\text{Res}(k)$, $SAT_r^n(x, z) \wedge REF_{r,m}^{n,k}(x, y)$, has $\text{Res}(k+1)$ refutations of size $(nr + kn^k m)^{O(1)}$.*

Proof sketch: It suffices to prove, for every $j \in \{1, \dots, m\}$, the following $(k+1)$ -disjunction

$$D_j \equiv \bigvee (y_{e_1,i_1,\dots,e_l,i_l,j} \wedge z_{i_1}^{(e_1)} \wedge \dots \wedge z_{i_l}^{(e_l)}),$$

where the disjunction ranges over $l \in \{1, \dots, k\}$, $e_1, \dots, e_l \in \{0, 1\}$, $i_1, \dots, i_l \in \{1, \dots, n\}$. The meaning of D_j is that at least one of the k -terms that appear in C_j is satisfied by the truth assignment z_1, \dots, z_n . \square

We want to point out that a small change in the encoding of the reflection principle for $\text{Res}(k)$ preserves the form of the feasible interpolation and has polynomial-size proofs in $\text{Res}(2)$. This change consists in adding new z -variables and new clauses to $SAT_r^n(x, z)$. These variables will encode the conjunctions of up to k literals on z_1, \dots, z_n . More precisely, the new variables are $z(l_1, \dots, l_s)$ for $s \leq k$, where l_i is a literal on z_1, \dots, z_n , as defined in Section 4. The new clauses are those exposed in Section 4 defining $z(l_1, \dots, l_s)$. The resulting formula is called $SAT_r^{n,k}(x, z)$. Again notice the new superindex k in SAT .

Theorem 7 *The reflection principle for $\text{Res}(k)$, $SAT_r^{n,k}(x, z) \wedge REF_{r,m}^{n,k}(x, y)$, has $\text{Res}(2)$ refutations of size $(n^k r + kn^k m)^{O(1)}$. Moreover, $SAT_r^{n,k}(x, z) \wedge REF_{r,m}^{n,k}(x, y)$ preserves the form of monotone feasible interpolation.*

Proof sketch: Again, it suffices to prove, for every $j \in \{1, \dots, m\}$, the following 2-disjunction

$$D_j \equiv \bigvee (y_{e_1,i_1,\dots,e_l,i_l,j} \wedge z(z_{i_1}^{(e_1)}, \dots, z_{i_l}^{(e_l)})),$$

where the disjunction ranges over $l \in \{1, \dots, k\}$, $e_1, \dots, e_l \in \{0, 1\}$, $i_1, \dots, i_l \in \{1, \dots, n\}$. \square

Let us note that the technique of the previous two theorems cannot be pushed to show that Resolution proves the reflection principle of $\text{Res}(k)$ while preserving the form of feasible interpolation. This is because the formula D_j in the proof has conjunctions that involve y and z -variables, which prevents us from defining their conjunction without mixing them.

Our next result shows the exact relationship between feasible interpolation and weak automatizability for $\text{Res}(k)$. In its proof, we will use what we have learned about reflection principles.

Theorem 8 For every constant $k \geq 2$, the following are equivalent:

- (i) Resolution is weakly automatizable,
- (ii) $\text{Res}(k)$ is weakly automatizable,
- (iii) $\text{Res}(k)$ has feasible interpolation.

Proof: (i) \Rightarrow (ii) Suppose Resolution is weakly automatizable. Then by Theorem 1, the canonical NP-pair of Resolution is polynomially separable. We claim that the canonical NP-pair of $\text{Res}(k)$ is also polynomially separable. Here is the separation algorithm: given F and a number m in unary, we build $F(k)$ and run the separation algorithm for the canonical pair of Resolution on $F(k)$ and $c \cdot k \cdot m$ in unary, where c is the hidden constant in Lemma 1. The running time of this algorithm is polynomial in the size of $F(k)$ and m , which is polynomial in the size of F and m because k is a constant. For the correctness, note that if F has a $\text{Res}(k)$ refutation of size m , then $F(k)$ has a Resolution refutation of size at most $c \cdot k \cdot m$ by Lemma 1, and the separation algorithm for the canonical pair of Resolution will return 0 on it. On the other hand, if F is satisfiable, so is $F(k)$ and the separation algorithm for Resolution will return 1 on it.

(ii) \Rightarrow (iii) This is Theorem 3.

(iii) \Rightarrow (i) This is a consequence of Theorem 5 and Theorem 4 because $k \geq 2$. \square

It is known that Resolution has feasible interpolation, and in fact monotone [Kra97a, Pud97]. However, it is not clear whether $\text{Res}(k)$ has feasible interpolation for $k \geq 2$. We know, however, that $\text{Res}(k)$ does not have monotone feasible interpolation (see [ABE02] and Corollary 1 in this paper). On the other hand, tree-like $\text{Res}(k)$ has feasible interpolation, even monotone, since Resolution polynomially simulates it [EGM02].

If k is no longer a constant, say $k = \log n$, the weak automatizability of Resolution would imply the feasible interpolation of $\text{Res}(k)$ in time $n^{O(k)}$. This is because computing $F(k)$ requires time $n^{O(k)}$. Therefore, in order to establish that Resolution is not weakly automatizable it would suffice to prove that $\text{Res}(\log n)$ does not have feasible interpolation in time $n^{O(\log n)}$.

6 Resolution: Lower Bound for the Reflection Principle

The next natural question to ask is whether the reflection principle for Resolution $SAT_r^n(x, z) \wedge REF_{r,m}^n(x, y)$ has refutations of moderate size in Resolution itself. Since Resolution has feasible interpolation [Kra97a, Pud97], a positive answer would imply that Resolution is weakly automatizable. Unfortunately, as the main result of this section shows, this will not happen. Before stating it we need two technical well-known results.

The first is a result due to Alon and Boppana. Let $F(m, k, k')$ be the set of monotone functions that separate k -cliques from k' -colorings on m nodes.

Theorem 9 ([AB87]) If $f \in F(m, k, k')$ where $3 \leq k' \leq k$ and $k\sqrt{k'} \leq m/(8 \log m)$, then

$$S^+(f) \geq \frac{1}{8} \left(\frac{m}{4k\sqrt{k'} \log m} \right)^{(\sqrt{k'}+1)/2},$$

where $S^+(f)$ is the monotone circuit size of f .

The second result that we need is due to Maciel, Pitassi and Woods. Let PHP_n^m be the set of clauses encoding the pigeonhole principle with m pigeons and n holes. That is, PHP_n^m is

$$p_{i,1} \vee \cdots \vee p_{i,n}, \quad (26)$$

$$\neg p_{i,k} \vee \neg p_{j,k}, \quad (27)$$

where $i, j \in \{1, \dots, m\}$, $i \neq j$, and $k \in \{1, \dots, n\}$.

Theorem 10 ([MPW02]) PHP_n^{2n} has $\text{Res}((\log n)^{O(1)})$ refutations of size $2^{(\log n)^{O(1)}}$.

In addition to these two results, we also need the fact that Resolution has monotone feasible interpolation as shown in [Kra97b, Pud97]. Recall the definition of monotone feasible interpolation in Section 2 just after Definition 7. We are now ready to state and prove the main result of this section. Its proof uses an idea due to Pudlák [Pud03].

Theorem 11 *Let s be a parameter. For a choice of n , r , and m of the order of a quasipolynomial $2^{(\log s)^{O(1)}}$, every Resolution refutation of $SAT_r^n(x, z) \wedge REF_{r,m}^n(x, y)$ requires size at least $2^{\Omega(s^{1/4})}$.*

Proof: Suppose for contradiction that there is a Resolution refutation of size $S = 2^{o(s^{1/4})}$. Let $k = s^{1/2}$, and let $COL_k(p, q)$ be the CNF formula expressing that q encodes a k -coloring of the graph on s nodes encoded by $\{p_{ij}\}$. An explicit definition is the following: For every $i \in \{1, \dots, s\}$, there is a clause of the form $\bigvee_{l=1}^k q_{il}$; and for every $i, j \in \{1, \dots, s\}$ with $i \neq j$ and $l \in \{1, \dots, k\}$, there is a clause of the form $\neg q_{il} \vee \neg q_{jl} \vee \neg p_{ij}$. Let $COL_k(G, q)$ be the result of replacing the p_{ij} -variables in $COL_k(p, q)$ by the values 1/0 depending on whether the edge $\{i, j\}$ is or is not in G . Obviously, if G is k -colorable, then $COL_k(G, q)$ is satisfiable, and if G contains a $2k$ -clique, then $COL_k(G, q)$ is unsatisfiable. More importantly, if G contains a $2k$ -clique, then the clauses of PHP_k^{2k} are contained in $COL_k(G, q)$. Now, for every graph G on s nodes, let $\mathcal{F}(G)$ be the clauses $COL_k(G, q)$ together with all clauses defining the extension variables for the conjunctions of up to $(\log k)^c$ literals on the q -variables. Here, c is a constant so that the $2^{(\log k)^{O(1)}}$ upper bound on PHP_k^{2k} of Theorem 10 can be done in $\text{Res}((\log k)^c)$. From Theorem 10 and Lemma 1, if G contains a $2k$ -clique, then $\mathcal{F}(G)$ has a Resolution refutation of size $2^{(\log k)^{O(1)}}$.

In the following, let n be the number of variables of $\mathcal{F}(G)$, let r be the number of clauses of $\mathcal{F}(G)$, and let $m = 2^{(\log k)^{O(1)}}$. Consider the formulas $SAT_r^n(x(G), z) \wedge REF_{r,m}^n(x(G), y)$ where $x(G)$ is the x -encoding of the formula $\mathcal{F}(G)$. By assumption, these formulas have Resolution refutations of size at most S . Let C be the monotone circuit that interpolates these formulas given by the monotone feasible interpolation of Resolution. The size of C is $S^{O(1)}$. Moreover, if G is k -colorable, then $SAT_r^n(x(G), z)$ is satisfiable, and C must return 0 on $x(G)$. Also, if G contains a $2k$ -clique, then $REF_{r,m}^n(x(G), y)$ is satisfiable, and C must return 1 on $x(G)$. Now, an anti-monotone circuit for separating $2k$ -cliques from k -colorings can be built as follows: given a graph G , build the assignment $x(G)$ (anti-monotonically, see below for details), and apply the monotone circuit given by the monotone interpolation. The size of this circuit is $2^{o(s^{1/4})}$, and this contradicts Theorem 9.

It remains to show how to build an anti-monotone circuit that, on input $G = \{p_{uv}\}$, produces $x(G)$, that is, the values of $x_{e,i,j}$ that correspond to the encoding of $\mathcal{F}(G)$ in terms of the x -variables. There are three types of clauses in $\mathcal{F}(G)$:

1. Clauses of the type $\bigvee_{l=1}^k q_{il}$: Let t be the numbering of this clause in $\mathcal{F}(G)$. Then, its encoding in terms of the x -variables is produced by outputting the constant 1 for $x_{0,q_{i1},t}, \dots, x_{0,q_{ik},t}$. The rest of the outputs of clause t are 0.
2. Clauses of the type $\neg q_{il} \vee \neg q_{jl} \vee \neg p_{ij}$: Let t be the numbering of this clause in $\mathcal{F}(G)$. The encoding is $x_{1,q_{il},t} = 1, x_{1,q_{jl},t} = 1, x_{1,p_{ij},t} = \neg p_{ij}$ and the rest are zero. Notice that this encoding is anti-monotone in the p_{ij} 's. Notice also that the encoded $\mathcal{F}(G)$ contains some p -variables (and not only q -variables as the reader might have expected) but this will not be a problem since the main properties of $\mathcal{F}(G)$ are preserved as we show below.
3. Finally, the clauses defining the conjunctions of up to $(\log k)^c$ literals are independent of G since only the q -variables are relevant here. Therefore, the encoding is done as in the first case.

The reader can easily verify that when G contains a $2k$ -clique, the encoded formula contains the clauses of PHP_k^{2k} and the definitions of the conjunctions up to $(\log k)^c$ literals. Therefore $REF(x(G), y)$ is satisfiable because PHP_k^{2k} has a small $\text{Res}((\log k)^c)$ refutation. Similarly, if G is k -colorable, the formula $SAT(x(G), z)$ is satisfiable by setting $z_{p_{ij}} = p_{ij}$ and $q_{il} = 1$ if and only if node i gets color l . Therefore, the main properties of $\mathcal{F}(G)$ are preserved, and the theorem follows. \square

An immediate corollary of the last two results is that $\text{Res}(2)$ is exponentially more powerful than Resolution. In fact, the proof shows a lower bound for the monotone interpolation of $\text{Res}(2)$ improving over the quasipolynomial lower bound in [ABE02].

Corollary 1 *Monotone circuits that interpolate $\text{Res}(2)$ refutations require size $2^{\Omega(s^{1/4})}$ on $\text{Res}(2)$ refutations of size $2^{(\log s)^{O(1)}}$.*

7 Short Proofs that Require Large Width

The width of a Resolution refutation is the number of literals of the largest clause. Ben-Sasson and Wigderson [BSW01] proved that the following relationship holds. Let F be a k -CNF formula with n variables and a Resolution refutation of size S . Then F has a Resolution refutation of width at most $\sqrt{n \log(S)} + k$. This suggests the following proof search procedure for Resolution: Derive all possible clauses using derived clauses of increasing width $1, 2, 3, \dots$ until the empty clause is found. The running time of this algorithm is bounded by $n^{O(\sqrt{n \log(S)+k})}$, which is subexponential if S is polynomial in n , say.

Bonet and Galesi [BG01] gave an example of a 3-CNF formula with small Resolution refutations that requires relatively large width (square root of the number of variables). This showed that the size-width trade-off of Ben-Sasson and Wigderson could not be improved. Also it showed that the algorithm of Ben-Sasson and Wigderson for finding Resolution refutations could perform very badly in the worst case. This is because their example requires large width, and the algorithm would take almost exponential time, while we know that there is a polynomial size Resolution refutation.

Alekhovich and Razborov [AR01] posed the question of whether more of these examples could be found. They say this is a necessary first step for showing that Resolution is not automatizable in quasipolynomial-time. Here we give a way of producing such bad examples for the algorithm. Basically the idea is finding CNFs that require sufficiently high width in Resolution, but that have polynomial size $\text{Res}(k)$ refutations for small k , say $k \leq \log n$. Then the example consists in adding to the formula the clauses defining the extension variables for all the conjunctions of at most k literals. Below we illustrate this technique by giving a large class of examples that have small Resolution refutations but that require large width. Moreover, deciding whether a formula is in the class is hard (no polynomial-time algorithm is known).

Let $G = (U \cup V, E)$ be a bipartite graph on the sets U and V of cardinality m and n respectively, where $m > n$. The G - PHP_n^m , defined by Ben-Sasson and Wigderson [BSW01], states that there is no matching from U into V . For every edge $(u, v) \in E$, let $x_{u,v}$ be a propositional variable meaning that u is mapped to v . The principle is then formalized as the conjunction of the following clauses:

$$\begin{aligned} x_{u,v_1} \vee \dots \vee x_{u,v_r} & \quad \text{for } u \in U, N_G(u) = \{v_1, \dots, v_r\}, \\ \neg x_{u,v} \vee \neg x_{u',v} & \quad \text{for } v \in V, u, u' \in N_G(v), u \neq u'. \end{aligned}$$

Here, $N_G(w)$ denotes the set of neighbors of w in G . Note that if G has left-degree at most d , then the width of the initial clauses is bounded by d .

Ben-Sasson and Wigderson proved that whenever G is expanding in a sense defined next, every Resolution refutation of G - PHP_n^m must contain a clause with many literals. We observe that this result is not unique to Resolution and holds in a more general setting. Before we state the precise result, let us recall the definition of expansion:

Definition 8 ([BSW01]) *Let $G = (U \cup V, E)$ be a bipartite graph where $|U| = m$, and $|V| = n$. For $U' \subset U$, the boundary of U' , denoted by $\partial U'$, is the set of vertices in V that have exactly one neighbor in U' ; that is, $\partial U' = \{v \in V : |N(v) \cap U'| = 1\}$. We say that G is (m, n, r, f) -expanding if every subset $U' \subseteq U$ of size at most r is such that $|\partial U'| \geq f \cdot |U'|$.*

The proof of the following statement is the same as in [BSW01] for Resolution.

Theorem 12 ([BSW01]) *Let P be a sound refutation system with all rules having fan-in at most two. Then, if G is (m, n, r, f) -expanding, every P -refutation of G - PHP_n^m must contain a formula that involves at least $r f / 2$ distinct literals.*

Now, for every bipartite graph G with $m \geq 2n$, let $\mathcal{C}(G)$ be the set of clauses defining G - PHP_n^m together with the clauses defining all the conjunctions up to $(\log n)^c$ literals, where c is a large constant so that the $2^{(\log n)^{O(1)}}$ upper bound on PHP_n^{2n} of Theorem 10 can be done in $\text{Res}((\log n)^c)$.

Theorem 13 *Let G be an $(m, n, \Omega(n/\log m), \frac{3}{4} \log m)$ -expander with $m \geq 2n$ and left-degree at most $\log m$. Then (i) $\mathcal{C}(G)$ has initial width $\log m$, (ii) any Resolution refutation of $\mathcal{C}(G)$ requires width at least $\Omega(n/(\log n)^c)$, and (iii) $\mathcal{C}(G)$ has Resolution refutations of size $2^{(\log n)^{O(1)}}$.*

Proof: Part (i) is obvious. For (ii), suppose for contradiction that $\mathcal{C}(G)$ has a Resolution refutation of width $w = o(n/(\log n)^c)$. Then, by the proof of Lemma 2, $G\text{-}PHP_n^m$ has a $\text{Res}((\log n)^c)$ refutation in which every $(\log n)^c$ -disjunction involves at most $(\log n)^c w = o(n)$ literals. This contradicts Theorem 12. For (iii), recall that PHP_n^m has a $\text{Res}((\log n)^c)$ refutation of size $2^{(\log n)^{O(1)}}$ by Theorem 10 since $m \geq 2n$. Now, setting to zero the appropriate variables of PHP_n^m , we get a $\text{Res}((\log n)^c)$ refutation of $G\text{-}PHP_n^m$ of the same size. By Lemma 1, $\mathcal{C}(G)$ has a Resolution refutation of roughly the same size, which is polynomial in the size of the formula. \square

8 Conclusions and Open Problems

It is surprising that the weak pigeonhole principle PHP_n^{2n} has short Resolution proofs when encoded with the clauses defining the extension variables for the small conjunctions. We exploited this fact in the proof of Theorem 11. The astute reader will notice that any small refutation in *any* Frege system could be translated into a short Resolution refutation when the CNF is enriched with clauses defining new variables for each of the intermediate formulas that are used in the Frege proof. However, the crucial difference of this approach is that the new encoding is not *canonical*: there is no uniform method to obtain it. As a matter of fact, although the pigeonhole principle has polynomial-size proofs in Frege, this approach would not allow us to improve the non monotone interpolation to a truly exponential lower bound because the $2k$ -clique of the graph is unknown to us beforehand.

We showed that the connection between weak automatizability of Resolution and interpolation of $\text{Res}(2)$ extends to $\text{Res}(k)$ for any $k \geq 2$. As a matter of fact, in order to prove that Resolution is not weakly automatizable, it suffices to show, for example, that $\text{Res}(\log n)$ does not have interpolation in subexponential-time. This leaves some hope of proving such a result with current techniques because $\text{Res}(\log n)$ is a fairly strong system (e.g. it proves the weak pigeonhole principle in quasipolynomial-size). However, let us note that the non-interpolation for bounded-depth Frege of [BDG⁺99] assuming that numbers cannot be factored in subexponential-time does not seem to establish the non-interpolation for any particular constant depth. Notice that $\text{Res}(\log n)$ is a depth-two system.

Of course, it remains open whether Resolution is weakly automatizable, or automatizable in quasipolynomial-time. Let us note that the width method for Resolution leads to some non-obvious results along these lines. For example, the width-based algorithm of Ben-Sasson and Wigderson solves *WEAK SAT* for tree-like Resolution in time $n^{O(\log m)}|F|^{O(1)}$, where n is the number of variables of F . This is quasipolynomial if m is polynomial in n . Similarly, it allows us to solve *WEAK SAT* for general Resolution in time $n^{O(\sqrt{n \log m})}|F|^{O(1)}$. This is subexponential if m is polynomial. The negative results of [AR01] do not rule out further improvements on these. Also, it would be interesting to get results of this type for other propositional proof systems.

Acknowledgment. We are grateful to Pavel Pudlák for stimulating discussions on the idea of Theorem 11.
