

# Goals

- To know the area of NLP and their applications
- To understand the problem associated to natural language processing and the syntactic and semantic analysis levels
- Basic knowledge of the programming of DCG analyzers

# Goals and areas of NLP

- The use of language to communicate among people it is one of the most important capacities of the human being
- The **goal** of Natural Language Processing (NLP) is to build computational systems that **understand** and/or **generate** human languages in any of its forms

# Goals and areas of NLP

To achieve this goal we need:

- To know how people **generates** correct and understandable expressions
- To know how people **understands** expressions
- To be able to **formalize** the knowledge and the processes needed to be implemented as a computational process that is tractable

# Multidisciplinarity

Areas associated to NLP:

- Linguistics
  - Computational linguistics
- Formal languages theory
  - Compilers
- Artificial Intelligence
  - Knowledge representation
  - Machine learning
  - Reasoning

# Understanding/Generation

- Two basic operations:

<Natural Language Interfaces>

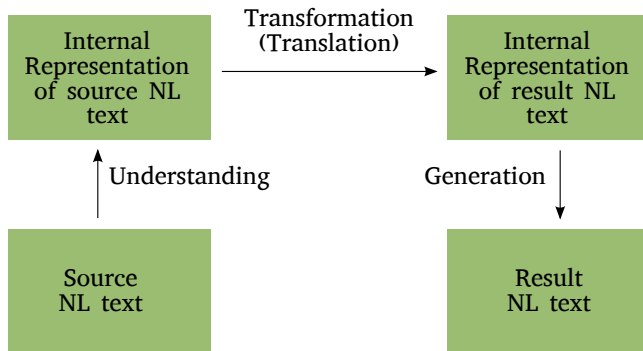

- The understanding of the query and the generation of the answer can be **oral**: speech recognition/synthesis

# Understanding/Generation

- Machine Translation:

<Machine Translation: Transfer Model>

- Translation can also be done from speech

# What is to understand?

*“Understand something means to transform from one representation to another, so this second representation corresponds to a set of actions that can be performed and the transformation guarantees that for each element to understand the correct action is done”*

*(Rich, 1991)*

# Understanding Natural Language

- To obtain the meaning of a text in order to perform the adequate actions
  - Query of a database
  - Actuators
  - Summarize a text
  - Translate a text

# How to understand Natural Language?

- Understanding needs
  - Extract the individual meaning of the words
  - Extract the meaning of the relations among words
  - Refer the literal meaning to the actuation context of the system:  
Metaphors, rhetoric, irony, intonation
- Tools
  - Analysis of the components of language at different levels

# Information for the analysis

- **lexical, syntactical, semantical** information
- Example:

**“Of course, you are talking about the urban restructuring of Barcelona”**

- It Has to be detected:
  - Individual words with meaning and connectives: Barcelona, restructuring, of, the, urban, talking
  - Gather information to know their role on the sentence and figure out possible meanings:
    - Morphosyntactic category: name, proper name, composed name, verb, article, etc.
  - Information about the relation among meanings to determine the global meanings
    - Syntactic role: subject, direct complement, etc.

# Levels of analysis

- Phonological
  - Treatment of sounds to found units of expression
- Textual
  - Segmentation of the text on tractable units (paragraphs, sentences, etc.)
  - Localization (identification) of words and lexical units
- Morphological
  - Formation of words considering derivation, composition, etc.
  - The morphological analysis gathers information to help in finding the roots and affixes (prefixes, suffixes, infixes) of the words
  - The word as a composition of morphemes
- Lexical
  - Considering a word as the meaning unit of the text
  - Obtaining lexical-semantic information (ontologies, semantic dictionaries)

## Levels of analysis (2)

- Syntactical (1): Detection of syntactically correct structures

**The cat eats a fish**

**The cat eat a fish**

- Syntactical (2): Extraction and representation of syntactically correct structures

## Levels of analysis (3)

- Logical

- Extraction of the literal meaning of the sentence
- Representation of the meaning using Predicate Calculus, frames, semantic networks, etc.
- In the case of Predicate Calculus: representation using variables, predicates, functions, constants, logical connectives, quantifiers, etc.

“The cat eats a fish”  $\equiv \exists x \exists y \text{Cat}(x) \wedge \text{Fish}(y) \wedge \text{Eats}(x, y)$

# Levels of analysis (4)

- Semantical

- Interpretation of the logical form: Relation among the logical entities (constants, variables, terms, etc.) and the real world (or its representation): objects of the domain
- Ex:
  - A cat is a feline,
  - fish is edible
  - The actor of eat must be a living being,
  - ...

# Levels of analysis (5)

- Pragmatic
  - Interpretation in a context (using implicit information)
  - ex: **The plane detected the school** (of fishes)
- Illocutionary
  - Detection of the intent of the speaker
  - Ex: “There are dirty dishes in the sink”
    - Is it a neutral declarative sentence?
    - Is it an invitation to perform an action? (“wash them!”)
    - Is it a complaint? (“You always forget to wash the dishes and I have to do it”)

# Problems of natural language (1)

- Lexical ambiguity
  - *The **bear** is climbing the tree*
  - **bear** could be a noun or a verb (POS tagging)
  - *The fisherman went to the **bank**.*
  - The slope of land adjoining a body of water? A business establishment in which money is kept? (WSD)
- Syntactical ambiguity
  - “The man went to the house with a boat”
  - “The chicken is ready to eat” (PP-attachment)

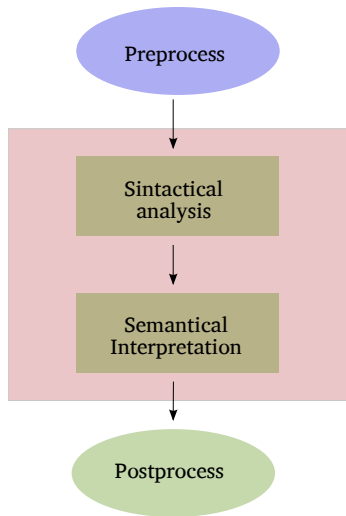

# Problems of natural language (2)

- Semantic ambiguity
  - “She gave a cake to the children”
  - 1 for all?, 1 for each? (scope of quantifiers)
  - “The green ideas sleep furiously” (Chomsky)
- References, ellipsis (pragmatic level)
  - “She gave her a book“ (...) “She didn’t like it“.
- Illocution: problems to find out the intent
  - “There are dirty dishes in the sink“ (wash them right now!)

# Analysis strategies

- The resolution to some of these ambiguities needs of the collaboration **among the levels of analysis**(an analyzer for each level?): more knowledge about the context
- Cooperation among analyzers:
  - Stratified: Sequential / waterfall
  - Global (parallel)

# Natural language processing

What is the capital of France?

# Preprocess

- Segmentation
- Location of units (words)
- Stemming, morphological analysis
- Morphosyntactic disambiguation (POS tagging)
- Semantic tagging
- Semantic disambiguation (WSD)
- Detection and classification of named entities (Named Entity Recognition, NER)

# Textual analysis

- Detection of tractable units: paragraphs and sentences
  - Simple methodologies,
    - Based on punctuation marks: “:”, “?”, “!”, “...”, etc.
    - Problems: acronyms, initials, etc.
  - Methodologies based on machine learning (classification)
    - Contextual information is used

# Lexical analysis: goals

- Detect words (units of meaning)
  - Needs to be able to recognize and fragment adequately the words:  
“The/ man/ checked in/ his/ luggage”
- Gather information and apply knowledge that reduces the cost of the next analysis processes
  - Associate grammatical categories
  - Associate semantical information to the lexical units (using ontologies, dictionaries, etc.)
  - Recognize and classify names and entities

# Problems of lexical analysis (1)

- **Correspondence among orthographical and grammatical word**
  - Domain knowledge is needed to detect cases like:
    - 1 orthographic word, many grammatical words (contractions in english), 2 orthographic word, 1 grammatical words (phrasal verbs in english)
- **Homonymy**
  - Same word and different grammatical categories: *bear* (verb to bear), *bear* (name) → Syntactical analysis
- **Polysemy**
  - Same word and category, different meanings: *bank*

## Problems of lexical analysis (2)

- **Acronyms**

- “When a PCB is generated it can inserted on a FIFO queue”
- “The cell’s DNA sample was identified by PRC, a process approved by the official UBI”

- **Abbreviations**

- “Dr. Smith talk about Nat. Lang. Proc.”

- **Formulas and measures**

- “add two mg. of DM-oxane and put it in a PVC vial”
- “Given that  $x=y*2 + k$ , where k is a constant”

- **Volume of information**

# Domain Knowledge

- Lexicons are the main source
  - “Lexical dictionaries”
  - They collect information that helps to recognize and categorize the place in the text of words
- We need to decide the kind of information that the dictionary needs:
  - Syntactical category
    - Determinant, proposition, proper nouns, substantive, verb, etc.
    - Granularity problem (verb -> transitive/intransitive)
  - Syntactical properties of agreement
    - gender (masculine/feminine)
    - number (singular/plural)
    - person (first, second...)
    - case (accusative,dative..)

# Domain Knowledge

- Other syntactical properties:
  - Possible kinds of complements of the verb
  - Prepositions that follow a word
- Semantical categories
- Morphological information
  - Derivation: prefixes/infixes/suffixes

# Morphological analysis

- Simple methods: list of forms with morphological information and their lemmas (formaries)
- Morphological analyzers:
  - Morpheme dictionaries: Dictionaries of roots, of suffixes, prefixes, etc.
  - Morphotactics: rules of morpheme combination
  - Phonological variations: changes combining the morphemes
- Types of analyzers
  - 1 level: FSA
  - 2 levels: FST
  - More than two levels: sequence of FSTs

# Result of the preprocess (lexical/morphological)

# Syntactical analysis

What is the capital of France?

```
(sentence
  (interrogative_sentence
    (interrogative_pronoun (what))
    (verb (is))
    (sj (the capital of France)))
  )
)
```

# Types of collaboration

- Without syntax
- Without semantics
- Sequential process (1):  
syntax | semantics
- Sequential process (2):  
{syntax + semantic filter} | semantics
- Parallel process:  
{syntax, semantics}

# Syntactical analysis (1)

- Goals
  - Determine if the sentence (textual unit) is syntactically correct
  - Create a syntactical structure with information that is needed by the semantical analysis and other analysis

## Syntactical analysis (2)

- Alphabet (vocabulary)  $\Sigma$
- Concatenation operation
- $\Sigma^*$  set of all the strings with symbols from  $\Sigma$  (free monoid)
- Language  $L \subseteq \Sigma^*$
- Given a string from  $\Sigma^*$   $w_1^n = w_1, \dots, w_n$   $w_i \in \Sigma$ , determine if  $w_1^n \in L$

# Defining the membership of a word

- Grammar
  - $G \Rightarrow L(G)$
  - $w_1^n \in L(G) ?$
- Language model
  - $P(w_1^n)$
  - if  $P(w_1^n) > 0 \Rightarrow w_1^n \in L$
- Corpus (sentences, patterns) that define the correct sentences
  - Syntactic dictionary
  - Rules of composition
- Rules of well formation
  - filters, negative grammars, ...

# The usual method: Grammar

- Constituents grammars
  - Derivation tree
- Dependency grammars
  - Dependency schemes
- Case grammars
  - Actant models  $\Rightarrow$  Semantic networks

# Syntagmatic Structure Grammars

- $\langle V, \Sigma, P, S \rangle$ 
  - $V$ : Non Terminal Vocabulary (Set of variables)
  - $\Sigma$ : Terminal vocabulary (alphabet)
  - $P$ : Set of productions
  - $S$ : Initial variable

$$\begin{aligned}\Sigma \cap V &= \emptyset \\ \Sigma \cup V &= \text{Vocabulary} \\ S &\in V\end{aligned}$$

# Types of grammars - Hierarchy of Chomsky (1)

## Type 0 **Unrestricted grammars**

- The elements of  $P$  are rewriting rules of the form

$$u \rightarrow w, \quad w, u \in (V \cup \Sigma)^*$$

- Corresponds to the recursively enumerable languages
- Recognized by Turing machines

## Type 1 **Context-sensitive Grammars**

- The length of the rule is limited

$$u \rightarrow w, \quad w, u \in (V \cup \Sigma)^* \text{ and } |u| \leq |v|$$

- Corresponds to Context sensitive languages
- Recognized by Linear Bounded Automaton

# Types of grammars - Hierarchy of Chomsky (2)

## Type 2 Context-free Grammars (CFG)

- The elements of  $P$  are rewriting rules restricted to:

$$A \rightarrow w, \quad A \in V, w \in (V \cup \Sigma)^*$$

- Corresponds to context free languages
- Recognized by non non-determinist push down automaton

## Type 3 Regular Grammars (RG)

- The elements of  $P$  are rewriting rules of the form:

$$A \rightarrow a$$

$$A \rightarrow aB, \quad A, B \in V, a \in \Sigma$$

- Corresponds to regular languages
- Recognized by finite state automaton

# Gramaticality

- A sentence  $w$  (a word from  $\Sigma^*$ ) belongs to the language generated by the grammar:

$$w \in L(G) \iff s \rightarrow_G^* w$$

- In other words, the grammar  $G$  can generate the word  $w$  using the productions from  $S$ .

# Building the grammar

- Define the terminals labels (tagset,  $\Sigma$ )
- Define the non terminal labels (V)
- Grammar rules (P)
  - Manual development
  - Automatic development: Grammatical inference (induction)
  - Semi automatic development

# Grammars for Natural Language Processing

- At least context free grammars
- Is NL a context free language?
- Enough? Usually NO
- Solution
  - CFG + {procedural context additions}
  - Logical and unification grammars
  - Grammars enhanced with statistical information
  - Lexicalized grammars

# Example of context free grammar

- (1) Sentence  $\rightarrow$  NG, VG
- (2) NG  $\rightarrow$  det, n
- (3) NG  $\rightarrow$  n
- (4) VG  $\rightarrow$  iv
- (5) VG  $\rightarrow$  tv, NG
- (6) det  $\rightarrow$  the | a
- (7) n  $\rightarrow$  cat | fish
- (8) tv  $\rightarrow$  eat | ...
- (9) iv  $\rightarrow$  eat | ...

## CFG + {Procedural Context Additions}

```
sentence -> question | command | ...
command  -> v,ng {imperative(1), command(1)}
ng        -> ngbase, [ngmods] | pn {agreement(1,2)}
ngbase    -> [det], n, [adjs] {agreement(1,2,3)}
adjs      -> adj, [adjs]
ngmods    -> ngmod, [ngmods]
ngmod     -> ps | ...
ps        -> prep, ng
pn        -> barcelona | valencia | ...
n         -> ticket | euromed | ...
v         -> give | buy | ...
det       -> a | the | ...
```

# Factors that intervene in the syntactical analysis process

- Grammar expressiveness (FSA, CFG, CFG+procedures)
- Coverage (lexicon, types of sentences)
- Sources of knowledge (linguistic knowledge)
- Analysis strategy (left to right, right to left, ...)
- Analysis direction (direction of writing, opposite direction of writing)
- Order applying the rules of the grammar (determinist, non determinist, preferences, ...)
- Treatment of ambiguity (use of semantic information)

# CFG analyzers and extensions

- Simplifications of CFG
  - $CFG \Rightarrow RG$ : Finite automata techniques: FSA
  - $CFG \Rightarrow DCFG$ : Determinist analyzers: LL, LR
- Extensions of Finite State Automat
  - $TN \Rightarrow RTN \Rightarrow ATN$  (Woods, 1970)
- Well Formed String Tables (WFST) , Charts
- Tabular methodologies: CKY, Earley (1970)
- Grammars of sentence structure: LSP (N. Sager, 1981), Diagram (A. Robinson, 1981)

# Transition networks (TN)

- Finite automata
- States associated to parts of the sentence
- Transitions: Labels referring to morphosyntactic categories
- Non determinism

# TN: limitations

- Limited to regular languages
- It is not really an analyzer: It **just recognizes**
- No-determinism  $\Rightarrow$  backtracking  $\Rightarrow$  Inefficient
- No distinction between grammar and analyzer
  - grammar  $\Rightarrow$  description of the syntactic model
  - analyzer (parser)  $\Rightarrow$  control

# Recurrent Transition Networks (RTN)

- Collection of labeled transition networks (TN)
  - Edges labeled with categories  $\Rightarrow$  as in TN
    - Terminal labels
  - Edges labeled with identifiers of TN
    - Non terminal labels
    - The end states of the TN return to the destination state of the transition that has called the TN
- RTN are weakly equivalent to CFG

## RTN: examples

# RTN: limitations

- The transitions only depend on categories (local/limited expressiveness)
  - Context free language
- Recognize but does not analyze
- Inefficient because of backtracking

# Augmented Transition Networks (ATN) (Woods, 1970)

- ATN = RTN with operations on the edges and use of variables
- Operations
  - **Conditions:** Filter transitions among states
  - **Actions:** Build output structures and transform the recognizer in an analyzer
- **Initializations**
- Allow to express contextual constraints

# ATN Example (Winograd, 1983)

Feature Dimensions: Number: Singular, Plural: default -empty-

## Initializations, Conditions and Actions:

NP-1:  $f$  Determiner  $g$

A: Set Number to the Number of \*

NP-4:  $g$  Noun  $h$

C: Number is empty or Number is the Number of \*

A: Set Number to the Number of \*

NP-5:  $f$  Pronoun  $h$

A: Set Number to the Number of \*

NP-6:  $f$  Proper  $h$

A: Set Number to the Number of \*

# ATN: limitations

- Adequate for top-down analysis but difficult for bottom-up analysis or hybrid analysis
- Operation redundancy because of backtracking
  - Inefficient
- Notational expressiveness problems:
  - Grammar is mixed with actions

# Charts (Kay, 1973, 1980)

- **Chart** = Directed graph that is built dynamically and incrementally while the analysis is performed
- The **nodes** correspond to the beginning, the end of the sentence and the separations among the words (N+1 nodes)

1                      2                      3                      4                      5  
●                      ●                      ●                      ●                      ●  
This                      is                      a                      sentence

- The redundancies during the analysis are reduced (Less Backtracking) by memorizing partially built structures
- **Problems:** space, construction time, only stores well formed components

# Charts (elements)

- The edges appear dynamically
- An edge from position  $i$  to  $j$  ( $j \geq i$ ) includes all the words that are between position  $i$  and  $j$ .
- Edges can be
  - **active** = goals or hypothesis to complete
  - **inactive** = components totally analyzed

# Charts: syntax (1)

- **Dotted rule:** rule of the grammar that has a dot inside the right side of the rule
- For example, from the rule  $A \rightarrow BCD$  can be derived the following dotted rules:

$A \rightarrow .BCD$  (corresponding to an active edge)

$A \rightarrow B.CD$  (corresponding to an active edge)

$A \rightarrow BC.D$  (corresponding to an active edge)

$A \rightarrow BCD.$  (corresponding to an inactive edge)

## Charts: syntax (2)

- **Edge** of a chart  $\langle i, j, X \rightarrow a.b \rangle$

$i, j$ : Source and destination nodes

$X \rightarrow ab$  rule of the grammar

$X \rightarrow a.b$  Dotted Rule

## Basic Combination Rule

The **basic combination rule** and the **ascendant** or **descendant** rules (or both at the same time) give the analysis method

**Active edge:**  $\langle i, j, A \rightarrow a.Bb \rangle$

**Inactive edge:**  $\langle j, k, B \rightarrow g. \rangle$

**Result:**  $\langle i, k, A \rightarrow aB.b \rangle$

# Ascendant Strategy

## Basic Rule

Each time that an inactive edge is added to the Chart  $\langle i, j, A \rightarrow a. \rangle$ , a new active edge  $\langle i, i, B \rightarrow .Ab \rangle$  has to be added to its leftmost vertice for each rules  $B \rightarrow Ab$  in the grammar

- **Initialization:** add all the inactive edges corresponding to the lexical categories (terminals).  
Ex:  $\langle 1, 2, Det \rightarrow the. \rangle$

# Descendant Strategy

## Basic Rule

Each time that an active edge is added to the Chart  $\langle i, j, A \rightarrow a.Bb \rangle$ , for each rule  $B \rightarrow b$  of the grammar an active edge  $\langle j, j, B \rightarrow .b \rangle$  has to be added to its rightmost vertice

- **Initialization:** the same than before but adding the active edge corresponding to the rule that recognizes a sentence.

Ex:  $\langle 1, 1, S \rightarrow .NG VG \rangle$

# Unification formalisms. Logic Grammars

- Unification based formalisms  $\subset$  Logic Grammars
- Usual implementation language: Prolog Characteristics
  - **Unification** as basic composition mechanism among constituents
  - **Syntagmatic approach** as basic way of grammatical description

# Notation

- Assertions (facts):  
man (X) ←
- Conditions (rules) (Consequent ← antecedent)  
mortal (X) ← home (X)
- Negations (Existential queries)  
← immortal(X)
- Contradictions  
□

# Grammatical analysis as automatic theorem proving

- The definition of the grammar and the lexicon as Horn clauses allow to apply resolution and reasoning by refutation as analysis mechanism

(1) sentence (X,Y)	$\leftarrow$ nomg(X,Z), verg(Z,Y)	<b>Grammar Rules</b>
(2) nomg(X,Y)	$\leftarrow$ det(X,Z), name(Z,Y)	
(3) verg(X,Y)	$\leftarrow$ ver(X,Y)	
(4) det(X,Y)	$\leftarrow$ the(X,Y)	<b>Lexicon</b>
(5) name(X,Y)	$\leftarrow$ dog(X,Y)	
(6) ver(X,Y)	$\leftarrow$ barks(X,Y)	

# Example (1)

1            2            3            4  
●    The    ●    dog    ●    barks    ●

(7) the(1,2)    ←

(8) dog(2,3)    ←

(9) barks(3,4)    ←

- THEOREM to prove sentence (1,4)
- Reasoning by refutation we have to negate...  
  ← **sentence(1,4)**
- ...and by resolution prove  
  □ (a contradiction)

# Example (2)

1            2            3            4  
 ●    The    ●    dog    ●    barks    ●

sentence(1,4) ←

(R1) (X=1, Y = 4) by unification

← nomg (1,Z), verg(Z,4)

(R2) and (R4) applied to nomg(1,Z) and det(1,U)

← det(1,U), name(U,Z), verg(Z,4)

← the(1,2), name(U,Z), ver(gZ,4)

(R7) (U = 2)

← name(2,Z), verg(Z,4)

(R5) and (R8) (Z = 3)

← dog(2,3), verg(3,4)

← verg(3,4)

(R3) and (R6) and(R9)

← ver(3,4)

← barks(3,4)

□

# Example (3)

1            2            3            4  
 ●    The    ●    dog    ●    barks    ●

```

sentence(1,4) ←
← nomg (1,Z), verg(Z,4)
← det(1,U), name(U,Z), verg(Z,4)
← the(1,2), name(U,Z), ver(gZ,4)
← name(2,Z), verg(Z,4)
← dog(2,3), verg(3,4)
← verg(3,4)
← ver(3,4)
← barks(3,4)
□

```

Direct interpretation in Prolog !!

# Unification analyzers

- Logic formalisms
  - Expressiveness and treatment
  - Definite Clause Grammars (DCG)
- Prolog as analyzer
- Unification
  - Term representation
  - Unification algorithm

# Definite Clause Grammars (DCG)

- The definite clause grammars allow to develop logic grammars as PROLOG programs
- PROLOG is a rule language that uses backward reasoning as resolution method
- A special syntax is defined to hide the treatment of sentences and to differentiate the elements of the grammar from the procedures used to augment the context free grammar
- The rules use variables to pass on information and to check the constraints that the grammar needs

# Definite Clause Grammars (Syntax)

- A grammar rule has the following syntax  
`left --> right1, right2, right3, ..., rightN`
- Each symbol of the grammar can have variables, they are used for different purposes (pass or get information from other rules, build a result, ...)
- The symbols from the input are consumed by using the operator square brackets and giving a list of variables and/or constants that have to be unified with the input  
`aaa --> [W], bbb`
- PROLOG code can be included using braces  
`aaa(W) --> [W], bbb(W), {number(W)}`
- To execute a DCG the main symbol of the grammar is invoked with two parameters, a list with the words in the sentence and an empty list  
`sentence([the,cat,eats,a,fish], [])`

# Definite Clause Grammars (Example)

```
analisis(X,Y):- asercion(X,Y).
```

```
asercion --> sn, verb, compl.
```

```
compl --> [].
```

```
compl --> prep, sn.
```

```
compl --> sn.
```

```
sn --> npr.
```

```
sn --> det, n.
```

```
verb --> [W], {verbo(W)}.
```

```
npr --> [W], {npropio(W)}.
```

```
n --> [W], {nombre(W)}.
```

```
det --> [W], {determ(W)}.
```

```
prep --> [W], {prepo(W)}.
```

```
npropio(clara).
```

```
npropio(maria).
```

```
npropio(barcelona).
```

```
nombre(hombre).
```

```
nombre(profesor).
```

```
nombre(libro).
```

```
determ(un).
```

```
determ(el).
```

```
verbo(esta).
```

```
verbo(rie).
```

```
verbo(piensa).
```

```
verbo(habla).
```

```
verbo(lee).
```

```
prepo(en).
```

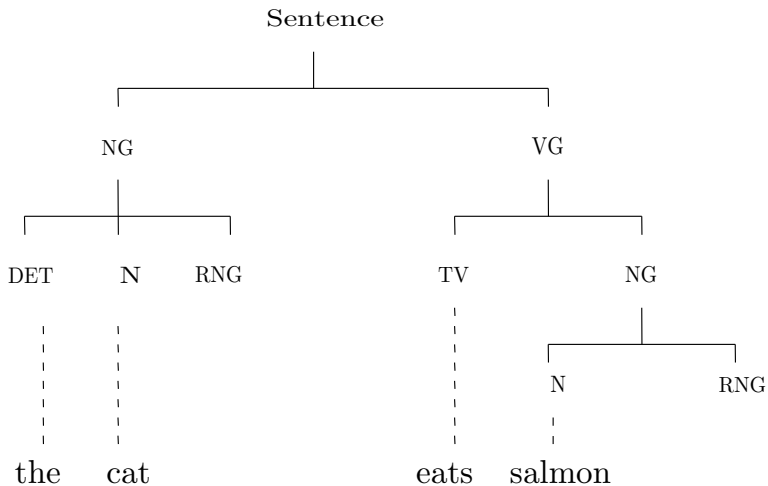

```
prepo(con).
```

```
prepo(de).
```

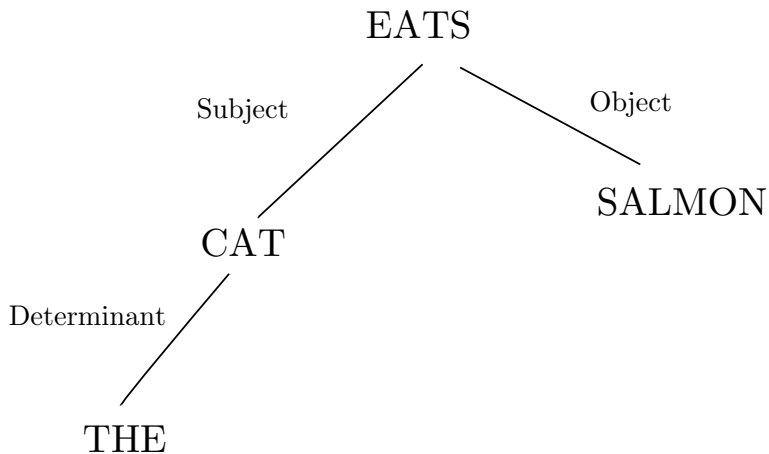

# Result of the syntactical analysis

- Tree of analysis
  - Structure of components
- Structure of dependencies
- Actant model
  - Semantic network
- Logical form

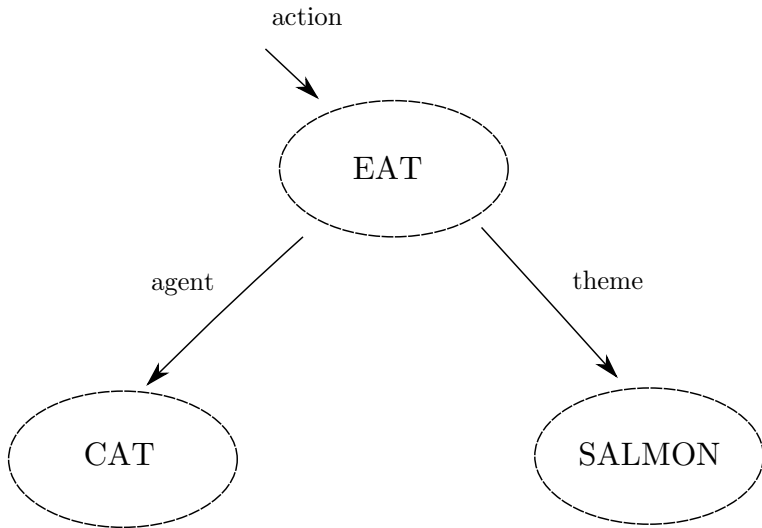

# Structure of components

# Structure of dependencies

# Actant model

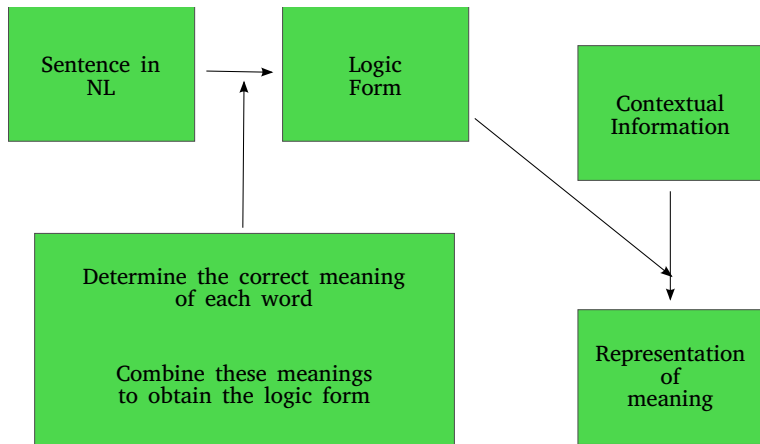

# Logic Form

$$\exists x(Cat(x) \wedge \exists y(Salmon(y) \wedge Eat(x, y)))$$

# Semantics

- Semantics studies the meaning of sentences
- Semantic interpretation (SI) is the process of extraction of this meaning

# Properties of the Semantic Model

- Compositive semantics: The representation of the semantic of an object has to be obtained from the semantic representation of its components:

$$SI = f(SI(\text{Syntactical Components}))$$

- Based on a theory
- Definition of a Semantic Representation System
- Syntax-Semantics interface
- SI has to be robust to ambiguity
- SI has to be able to treat complex things like: *Quantification, modality, negation*

# Two problems

- Meaning representation
- Semantic interpretation

# Representation of meaning (1)

## input:

Who leads the PSOE?

## Logic form:

```
(question
  (referent (X))
    (X instance (X, person)
      (el1 (Y instancia(Y, political_party) name(Y, "PSOE"))
        (Z instance(Z, lead)
          present(Z)
          value_prop(Z, agent, X)
          value_prop(Z, pacient, Y))))))
```

## Representation of meaning (2)

- This formula has four different informations:
  - Logical structure
  - Conceptual content (semantic)
  - Acts of speech
  - Pragmatic annotations
- The formalism should have enough expressive capacity to guarantee the description of all four kinds of information

# Representation of meaning (3)

- Representation formalisms:
  - Predicate calculus (Modal logic, Temporal Logic, Description Logic, ...)
    - Usually in clausal form
  - Other logic formalisms
  - Semantic networks
  - Frames

# Representations based on Logic

- A vocabulary of **predicates** with their arity (number of arguments and sometimes their types).
- A vocabulary of **constants** and **variables**.
- A set of logic **connectives**.
- A vocabulary of **functions** with their arity.
- A set of **quantifiers** that will affect the predicates that have to (or can) be quantified.

# Semantic interpretation

- Interaction with the syntactical analysis:
  - Sequential process (1): syntax | semantics
  - Sequential process (2): {syntax + semantic filter} | semantics
  - Parallel process: {syntax, semantics}
- Methods for obtaining the composition
  - Composition function
  - SI activation

# Example of composition function

- Interpretation by lambda evaluations:

$$(\textit{lambda}(x)(\dots)) = (\lambda(x)(\dots))$$

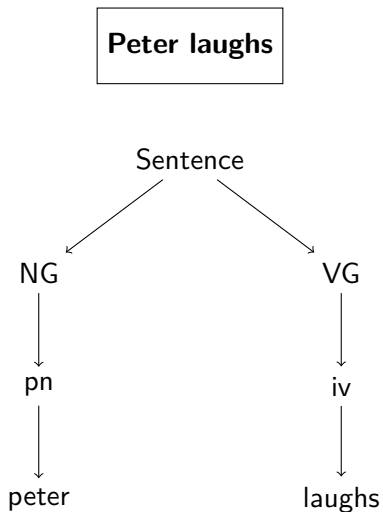

## Grammar

Sentence	← NG VG (2 1)
NG	← pn (1)
VG	← iv (1)
VG	← tv NG (1 2)

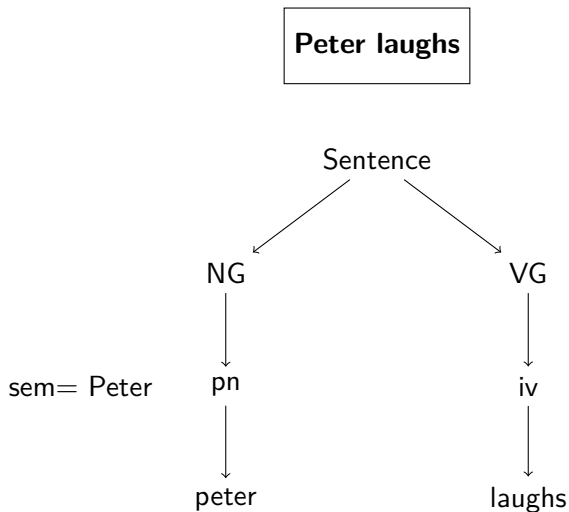

## Lexicon

Peter	← np, peter
Mary	← np, mary
laughs	← vi, $(\lambda(x) (\textit{laughs}(x)))$
loves	← vt, $((\lambda(x) (\lambda(y), \textit{loves}(y, x))))$

# Natural Language Processing

What is the capital of France?

```

(sentence
  (interrogative_sentence
    (interrogative_pronoun (what))
    (verb (is))
    (sj (the capital of France)))
  )
)

```

question(X), capital(X,france)

# Postprocess

- Reference resolution
- Semantical-pragmatic analysis
- Illocutive analysis: Intention recognizing

# NLP now (1990-)

- **Empirical** NLP
- Based on textual **corpora**
- **Statistical** processing vs. **Linguistic** processing
- **Combination** of linguistics and statistical models
- Application of **Machine Learning** methods to model language

# Classical applications

- Based on **text**
  - Automatic translation
  - Extraction of information from text
- Based on **dialogs**
  - Natural language interfaces
  - Data base queries
  - Telephonic information services
  - Intelligent tutor systems

# Applications based on document collections

- Sources
  - Document corpora
  - Internet
- Information retrieval
  - The linguistic component improves precision
  - Language independent access and retrieval
- Document categorization
  - Document routing: Press agencies, e-mail classification, etc.
  - Document filtering: Commercial e-mail, netnews, etc.
  - Automatic (Re)organization of document collections: Textual databases, Internet, etc.
  - Topic Detection and Tracking

# Applications based on document collections

- Extraction of information from the Web
  - Integration of information
  - Information search
  - Clustering and detection of relations inter/intra document
  - Routing and classification of documents
  - Document filtering
  - Corpora compilation
- Automatic summarization
- Question Answering

- + ! ! The chicken has a crispy skin and perfectly cooked, steamy meat ; the pork is slow-cooked and tender.
- + ! ! The garlic entrees are always great
- + ! ! The food quality was outstanding
- + ! ! Service is great and friendly never had an empty glass..
- + ! ! Serving up large portions of really good authentic cuban food
- + ! ! I recommend this place.

# Question Answering

The screenshot displays the WolframAlpha interface. At the top, the logo features a red starburst icon followed by the text "WolframAlpha" in a serif font, with "computational knowledge engine" in a smaller sans-serif font to its right. Below the logo, the text "Enter what you want to calculate or know about:" is followed by two links: "Examples" and "Random". A search input field contains the text "who is the current president of the United States of America" and has a small orange square button with a white minus sign on its right side. Below the input field, the "Input interpretation:" section shows two grey buttons with the text "United States" and "President". The "Result:" section below that displays the text "Barack Obama".
