

# Program Verification Using Automatic Generation of Invariants

**Enric Rodríguez-Carbonell**

**Universitat Politècnica  
de Catalunya  
Barcelona**

**Deepak Kapur**

**University  
of New Mexico  
Albuquerque**

# Plan of the Talk

## 1. Introduction

## 2. Invariant Generation

- General method for discovering invariants in loops without nesting
- Conditions to compute strongest possible invariant expressible in assertion language
- Instantiation for finding invariant polynomial equalities

## 3. Program Verification

- Application with prototype verifier

## 4. Future Work and Conclusions

# Introduction

## Need for Software Verification

- **Critical systems**
  - safety
  - security
  - economy
- **Finding errors as soon as possible.** See Microsoft's *Software Productivity Tools* group: **verification pays off**
- **Main classes of techniques:**
  - Model checking
  - Abstract Interpretation
  - Theorem Proving

## Introduction

# Verification by Theorem Proving (1)

- Program behaviour specified by *pre-postconditions*
- Formulas called *verification conditions* encoding correctness of program are generated
- Verification conditions proved by *theorem prover*
- Program must also be annotated with *loop invariants*

**loop invariants fundamental for program verification**

## Introduction

### Verification by Theorem Proving (2)

```
{Pre:  $X \geq 0 \wedge Y \geq 0$ }  
 $x := X; y := Y; z := 0;$   
{Inv:  $I(x, y, z, X, Y)$ }  
while ( $y \neq 0$ ) do  
  if ( $y \bmod 2 = 0$ ) then  
     $x := 2 * x; y := y \text{ div } 2;$   
  else  
     $y := y - 1; z := x + z;$   
  end if  
end while  
{Post:  $z = X * Y$ }
```

#### VERIFICATION CONDITIONS

- Precondition implies invariant
- Invariant preserved in if branch
- Invariant preserved in else branch
- Invariant implies postcondition

# Introduction

## Verification by Theorem Proving (3)

```
{Pre:  $X \geq 0 \wedge Y \geq 0$ }  
 $x := X; y := Y; z := 0;$   
{Inv:  $I(x, y, z, X, Y)$ }  
while ( $y \neq 0$ ) do  
  if ( $y \bmod 2 = 0$ ) then  
     $x := 2 * x; y := y \text{ div } 2;$   
  else  
     $y := y - 1; z := x + z;$   
  end if  
end while  
{Post:  $z = X * Y$ }
```

### VERIFICATION CONDITIONS

- $X \geq 0 \wedge Y \geq 0 \Rightarrow I(X, Y, 0, X, Y)$
- $I(x, y, z, X, Y) \wedge y \bmod 2 = 0 \wedge y \neq 0 \Rightarrow I(2 * x, y \text{ div } 2, z, X, Y)$
- $I(x, y, z, X, Y) \wedge y \bmod 2 = 1 \wedge y \neq 0 \Rightarrow I(x, y - 1, x + z, X, Y)$
- $I(x, y, z, X, Y) \wedge y = 0 \Rightarrow z = X * Y$

# Introduction

## Verification by Theorem Proving (4)

- **Problems** in the past
  1. Provers **too weak** and needed too much interaction
  2. Annotation burden: need to supply invariants **by hand**
- **Solutions** in the present
  1. Spectacular **improvement** of automated reasoning
  2. **Automatic** invariant generation

# Plan of the Talk

1. **Introduction**
2. **Invariant Generation**
3. **Program Verification**
4. **Future Work and Conclusions**

# Invariant Generation

## Related Work (1)

- **Dynamic** approaches (e.g. Daikon) [Ernst et al.'01.]
  1. Run programs on sample inputs
  2. Find **candidate** invariants from set of templates
- **Static** approaches
  1. Operate on program text
  2. Invariants found are **correct**
    - Top-down: *backward* propagation of *postcondition* [Müller-Olm & Seidl'03,'04]
    - Bottom-up: *forward* propagation of *precondition* (see next slide)
    - Constraint-based methods [Colón et al.'03, Sankaranarayanan et al.'04, Kapur'04]

# Invariant Generation

## Related Work (2)

### Bottom-up approach

- **Abstract Interpretation** [Cousot & Cousot'77]
  - Interval ranges [Cousot & Cousot'76]
  - Linear inequalities [Cousot & Halbwachs'78]
  - Congruences [Granger'89,'91,Masdupuy'92]
  - Polynomial equalities  
[Rodriguez-Carbonell & Kapur'04,Colón'04]
- **Difference Equations Method** [Elspas et al.'72]
  1. Find program states using *difference equations*
  2. Eliminate loop counters

# Invariant Generation

## Overview

- **GOAL:** Generation of invariants for loops without nesting

```
while  $E(\bar{x})$  do
  if  $C_1(\bar{x})$  then  $\bar{x} := f_1(\bar{x});$ 
  ...
  else if  $C_i(\bar{x})$  then  $\bar{x} := f_i(\bar{x});$ 
  ...
end if
end while
```

- **MEANS:** Forward propagation with acceleration
  - *Improves the number of iterations* before termination
  - *Reduces loss of information* involved in approximations
- **INSTANTIATION:** polynomial equalities as invariants

# Invariant Generation

## Forward Propagation (1)

```

{ R(x̄) }
while E(x̄) do
  if C1(x̄) → x̄ := f1(x̄);
  ...
  [] Ci(x̄) → x̄ := fi(x̄);
  ...
end if
end while

```

- Post-states of  $i$ -th branch, 1 step  $Post_i(R)$ :

$$Post_i(R) = \{ \exists \bar{y} (\bar{x} = f_i(\bar{y}) \wedge R(\bar{y}) \wedge E(\bar{y}) \wedge C_i(\bar{y})) \}$$

- Post-states of  $i$ -th branch, any number of steps  $Post_i^*(R)$ :

$$Post_i^*(R) = \left\{ \bigvee_{s=1}^{\infty} \exists \bar{y} (\bar{x} = f_i^s(\bar{y}) \wedge R(\bar{y}) \wedge \bigwedge_{t=0}^{s-1} E(f_i^t(\bar{y})) \wedge C_i(f_i^t(\bar{y}))) \right\}$$

# Invariant Generation

## Forward Propagation (2)

Fixpoint procedure for generating invariants

```
 $R' := false;$   
 $R := R_0;$   
while  $R' \not\Rightarrow R$  do  
     $R' := R;$   
     $R := R \vee (\bigvee_{i=1}^n Post_i^*(R));$   
end while
```

# Invariant Generation

## Forward Propagation (3)

To make procedure realizable, in assertion language we need to:

- Over-approximate  $\vee$
- Over-approximate  $Post_i^*$
- Check equivalence of formulas

The procedure computes the *strongest invariant* if additionally

- There is *strongest invariant* in the language
- The over-approximation of  $\vee$  is the *best possible*
- The over-approximation of  $Post_i^*$  is the *best possible*

# Invariant Generation

## Forward Propagation (4)

To make procedure realizable, in assertion language we need to:

- Over-approximate  $\forall$  → **Disjunctively closed**
- Over-approximate  $Post_i^*$  → **Quantifier elimination**
- Check equivalence of formulas → **Equivalence checking**

The procedure computes the *strongest invariant* if additionally

- There is strongest invariant in the language → **Expressive**
- The over-approximation of  $\forall$  is the best possible
- The over-approximation of  $Post_i^*$  is the best possible

# Invariant Generation

## Polynomial Equalities as Invariants (1)

Instance of method: **conjunctions of polynomial equalities**

Satisfy all requirements:

- **Over-approximation of  $\forall$** : intersection of ideals of polynomials exactly expresses  $\forall$
- **Over-approximation of  $Post_i^*$** : elimination of variables gives the best approximation possible
- **Equivalence checking**: computation of Gröbner bases
- Existence of **strongest invariant**: by Hilbert's basis theorem

# Invariant Generation

## Polynomial Equalities as Invariants (2)

```
 $x := X; y := Y; z := 0;$   
while ( $y \neq 0$ ) do  
  if ( $y \bmod 2 = 0$ ) then  
     $x := 2 * x; y := y \text{ div } 2;$   
  else  
     $y := y - 1; z := x + z;$   
  end if  
end while
```

### TRACE

1.  $x = X \wedge y = Y \wedge z = 0$
2.  $x * z = X * z \wedge$   
 $z + x * y = Y * X \wedge$   
 $z * y * X + z^2 = z * Y * X$
3.  $z + x * y = X * Y$
4.  $z + x * y = X * Y$

# Plan of the Talk

4. Future Work and Conclusions

# Program Verification

Scheme of an Implementation for the  
**Verification of Imperative Programs**

# Program Verification

## Verification Condition Generator (1)

- **INPUT:** imperative programs annotated with pre/postconditions
- **PROGRAMMING LANGUAGE**
  - Integer variables
  - Arithmetic operators:  $+$ ,  $*$ , **div**, **mod**
  - Procedure calls
- **SPECIFICATION LANGUAGE**
  - Untyped first-order logic with interpreted symbols
  - Interpreted function symbols:  $+$ ,  $*$ , **div**, **mod**, **lcm**, **gcd**, **exp**
  - Interpreted predicate symbols:  $=$ ,  $\geq$ ,  $>$

# Program Verification

## Verification Condition Generator (2)

```
{Inv:  $z + x * y = X * Y$ }
{ $y \neq 0 \wedge y \bmod 2 = 0 \Rightarrow z + (2 * x) * (y \text{ div } 2) = X * Y$ }
while ( $y \neq 0$ ) do
  { $y \bmod 2 = 0 \Rightarrow z + (2 * x) * (y \text{ div } 2) = X * Y$ }
  if ( $y \bmod 2 = 0$ ) then
    { $z + (2 * x) * (y \text{ div } 2) = X * Y$ }
     $x := 2 * x$ ;
    { $z + x * (y \text{ div } 2) = X * Y$ }
     $y := y \text{ div } 2$ ;
    { $z + x * y = X * Y$ }
  else
    ...
end while
{ $z + x * y = X * Y$ }
```

### VERIFICATION CONDITION

$$z + x * y = X * Y \wedge y \neq 0 \wedge y \bmod 2 = 0 \Rightarrow \\ z + (2 * x) * (y \text{ div } 2) = X * Y$$

# Program Verification

## Theorem Prover (1)

- First-order general theorem prover SPASS **unsatisfactory**
- **Better** results with our *ad-hoc* prover
  - **Simplification**: rewriting until getting *true*
  - Conditional rewriting  $\longrightarrow$  **strategies** for proving theorems
  - **Knowledge incorporated** about integer numbers
  - Implemented in Prolog

# Program Verification

## Theorem Prover (2)

$$z + x * y = X * Y \wedge y \neq 0 \wedge y \bmod 2 = 0 \Rightarrow \\ z + \underline{(2 * x) * (y \text{ div } 2)} = X * Y$$

↓ [commutativity, associativity of \*]

$$z + x * y = X * Y \wedge y \neq 0 \wedge y \bmod 2 = 0 \Rightarrow z + x * \underline{(2 * (y \text{ div } 2))} = X * Y$$

↓ [ $y \bmod 2 = 0 \Rightarrow 2 * (y \text{ div } 2) = y$ ]

$$\underline{z + x * y = X * Y} \wedge y \neq 0 \wedge y \bmod 2 = 0 \Rightarrow \underline{z + x * y = X * Y}$$

↓ [goal is in the premises]

*true*

# Plan of the Talk

1. **Introduction**
2. **Invariant Generation**
3. **Program Verification**
4. **Future Work and Conclusions**

# Future Work

- Verification condition generator: **new data structures**
  - Arrays
  - Lists/stacks/queues
  - Pointers
- Theorem prover: **domain-specific theorem provers**
  - CVC Lite
  - Simplify
  - ICS
  - Decision procedures in our research group
- Loop invariant generator:  
**specialized for data structures of interest**

# Conclusions

- **General technique** for discovering invariants in **loops without nesting**
- Shown conditions to compute the ***strongest possible invariant*** expressible in the assertion language
- Instantiated for finding **invariant polynomial equalities**
- Applied to **program verification** with prototype verifier
