Complexity Analysis of Algorithms

Jordi Cortadella
Department of Computer Science
Estimating runtime

What is the runtime of $g(n)$?

```c
void g(int n) {
    for (int i = 0; i < n; ++i) f();
}
```

Runtime($g(n)$) $\approx n \cdot$ Runtime($f()$)

```c
void g(int n) {
    for (int i = 0; i < n; ++i)
        for (int j = 0; j < n; ++j) f();
}
```

Runtime($g(n)$) $\approx n^2 \cdot$ Runtime($f()$)
What is the runtime of \( g(n) \)?

```c
void g(int n) {
    for (int i = 0; i < n; ++i)
        for (int j = 0; j <= i; ++j) f();
}
```

Runtime\((g(n))\) \( \approx \) \((1 + 2 + 3 + \cdots + n) \cdot \text{Runtime}(f())\)
\[\approx \frac{n^2 + n}{2} \cdot \text{Runtime}(f())\]
Complexity analysis

• A technique to characterize the execution time of an algorithm independently from the machine, the language and the compiler.

• Useful for:
  – evaluating the variations of execution time with regard to the input data
  – comparing algorithms

• We are typically interested in the execution time of large instances of a problem, e.g., when \( n \to \infty \), (asymptotic complexity).
Big O

• A method to characterize the execution time of an algorithm:
  – Adding two square matrices is $O(n^2)$
  – Searching in a dictionary is $O(\log n)$
  – Sorting a vector is $O(n \log n)$
  – Solving Towers of Hanoi is $O(2^n)$
  – Multiplying two square matrices is $O(n^3)$
  – ... 

• The $O$ notation only uses the dominating terms of the execution time. Constants are disregarded.
• Let $T(n)$ be the execution time of an algorithm when the size of input data is $n$.

• $T(n)$ is $O(f(n))$ if there are positive constants $c$ and $n_0$ such that $T(n) \leq c \cdot f(n)$ when $n \geq n_0$. 
Let $T(n) = 3n^2 + 100n + 5$, then $T(n) = O(n^2)$

Proof:
- Let $c = 4$ and $n_0 = 100.05$
- For $n \geq 100.05$, we have that $4n^2 \geq 3n^2 + 100n + 5$

Thus, $T(n)$ is also $O(n^3)$, $O(n^4)$, etc.

Typically, the smallest complexity is used.

</tbody>
</table>
This is often the practical limit for big data
Summary

• Complexity analysis is a technique to analyze and compare algorithms (not programs).

• It helps to have preliminary back-of-the-envelope estimations of runtime (milliseconds, seconds, minutes, days, years?).

• Worst-case analysis is sometimes overly pessimistic. Average case is also interesting (not covered in this course).

• In many application domains (e.g., big data) quadratic complexity, $O(n^2)$, is not acceptable.

• Recommendation: avoid last-minute surprises by doing complexity analysis before writing code.
